ALMOST AUTOMORPHIC SOLUTIONS OF DYNAMIC EQUATIONS ON TIME SCALES

CARLOS LIZAMA AND JAQUELINE G. MESQUITA

Abstract. In the present work, we introduce the concept of almost automorphic functions on time scales and present the first results about their basic properties. Then, we study the nonautonomous dynamic equations on time scales given by $x^\Delta(t) = A(t)x(t) + f(t)$ and $x^\Delta(t) = A(t)x(t) + g(t, x(t))$, $t \in \mathbb{T}$ where $\mathbb{T}$ is a special case of time scales that we define in this article. We prove a result ensuring the existence of an almost automorphic solution for both equations, assuming that the associated homogeneous equation of this system admits an exponential dichotomy. Also, assuming the function $g$ satisfies the global Lipschitz type condition, we prove the existence and uniqueness of an almost automorphic solution of the nonlinear dynamic equation on time scales. Further, we present some applications of our results for some new almost automorphic time scales. Finally, we present some interesting models which our main results can be applied.

1. Introduction

The theory of time scales is a recent theory which started to be developed by Stefan Hilger, on his doctoral thesis (see [34]). This theory represents a powerful tool for applications to economics, populations models, quantum physics among others. See, for instance, [4], [19] and [36]. Because of this fact, it has been attracting the attention of many mathematicians (see [1], [6], [10], [22], [23], [24], [26], [27], [45], [46], [47], [48], for instance and the references therein) and the interest in the subject remains growing.

Since time scale is any closed nonempty subset of $\mathbb{R}$, the theory of dynamic equations on time scales allows to unify several developments in evolution equations, depending on the chosen time scale. For instance, if $\mathbb{T} = \mathbb{Z}$, we have a result for difference equations. On the other hand, taking $\mathbb{T} = \mathbb{R}$, we obtain a result for differential equations. We point out that this theory can also describe continuous-discrete hybrid processes, which have several important applications. For instance, the continuous-discrete hybrid processes can be used to investigate option-pricing and stock dynamics in finance, the frequency of markets and duration of market trading in economics, large-scale models of DNA dynamics, gene mutation fixation, electric circuits, populations models, among others. See, for instance, [13], [19], [37], [50], [36] and the references therein.

Moreover, this theory can be used to study quantum physics. Choosing the time scale equal to $q^\mathbb{Z} \cup \{0\}$, $q > 1$, we obtain a result for quantum calculus, which is a fundamental tool to study quantum physics. See [11] and [12] for more details.

Recently, the qualitative properties of the solutions of dynamic equations on time scales have been extensively investigated, specially concerning their periodicity. Periodic dynamic equations on time scales have been treated by several mathematicians. See, for instance, [1], [2], [6], [10], [42] and the references therein. On the other hand, almost periodicity is a recent concept in the literature of time scales. It was formally introduced by Y. Li and C. Wang (2011) in [40] and based on it, some results concerning almost periodicity for dynamic equations on time scales were proved (see [39]). However, to the best of our knowledge, the concept of almost automorphic functions on time scales has not been introduced in the literature until now.

The theory of continuous almost automorphic was introduced by S. Bochner in relation to some aspects of differential geometry (see [7], [8] and [9]) and after that, this theory has been attracting the attention of several mathematicians and the interest in this topic still increasing. See, [14], [15], [16], [17], [20], [29], [30], [43], for instance and the references therein.

Motivated by this fact, the main goal of this paper is to introduce the concept of almost automorphic functions on time scales and to start the investigation of existence and uniqueness of almost automorphic solutions of dynamic equations. More precisely, we study the non-autonomous dynamic equations on time scales given by

\[ x^\Delta(t) = A(t)x(t) + f(t), \quad t \in \mathbb{T}, \]

where \( A \in \mathcal{R}^{n \times n}(\mathbb{T}, \mathbb{R}^n) \) and \( f \in \mathcal{C}_{rd}(\mathbb{T}, \mathbb{R}^n) \).

We prove the existence of an almost automorphic solution of (1.1), assuming the associated homogeneous equation of (1.1) admits an exponential dichotomy and \( \mathbb{T} \) is an invariant under translations time scale, concept that we introduce here for the first time. In passing, we show that in these time scales the graininess function have the remarkable property of to be automatically almost automorphic. Also, we suppose \( A \in \mathcal{R}(\mathbb{T}, \mathbb{R}^{n \times n}) \) is almost automorphic and nonsingular matrix function, the sets

\[ \{A^{-1}(t)\}_{t \in \mathbb{T}} \quad \text{and} \quad \{(I + \mu(t)A(t))^{-1}\}_{t \in \mathbb{T}} \]

are bounded and \( f \in \mathcal{C}_{rd}(\mathbb{T}, \mathbb{R}^n) \) is almost automorphic function.

After that, we consider the semilinear dynamic equation on time scales given by

\[ x^\Delta(t) = A(t)x(t) + f(t, x(t)), \quad t \in \mathbb{T}, \]

where \( A \in \mathcal{R}(\mathbb{T}, \mathbb{R}^{n \times n}) \), \( f \in \mathcal{C}_{rd}(\mathbb{T} \times \mathbb{R}^n, \mathbb{R}^n) \) and \( \mathbb{T} \) is an invariant under translations time scale.

We also obtain the existence and uniqueness of an almost automorphic solution of (1.3), we assume the associated homogeneous equation of (1.3) admits an exponential dichotomy and \( A \in \mathcal{R}(\mathbb{T}, \mathbb{R}^{n \times n}) \) is almost automorphic and nonsingular matrix function, the sets in (1.2) are bounded and \( f \in \mathcal{C}_{rd}(\mathbb{T} \times \mathbb{R}^n, \mathbb{R}^n) \) is almost automorphic function with respect to first variable and satisfies the global Lipschitz condition with respect to the second variable.

Moreover, we present some applications of our results for new and interesting invariant under translations time scales. Finally, we present interesting models which our results can be applied.

The present paper is organized as follows. The second section is devoted to present the preliminaries results concerning the theory of time scales. In the third section, we prove
some properties for almost automorphic functions on time scales and present some examples. The fourth section is devoted to present some basic concepts and main results concerning product integration on time scales. The fifth section brings a result which ensures the existence of almost automorphic solutions for linear dynamic equations on time scales. In the sixth section, we prove an existence and uniqueness of almost automorphic solutions for semilinear dynamic equations on time scales. Finally, the last section is devoted to present some interesting examples and applications of our main results.

2. Preliminaries

In this section, we present some basic concepts and results concerning time scales which will be essential to prove our main results. For more details, the reader may want to consult [11] and [12].

Let $\mathbb{T}$ be a time scale, that is, closed and nonempty subset of $\mathbb{R}$. For every $t \in \mathbb{T}$, we define the forward and backward jump operators $\sigma, \rho : \mathbb{T} \rightarrow \mathbb{T}$, respectively, as follows:

$$
\sigma(t) = \inf\{s \in \mathbb{T}, \ s > t\} \quad \text{and} \quad \rho(t) = \sup\{s \in \mathbb{T}, \ s < t\}.
$$

In this definition, we consider $\inf \emptyset = \sup \mathbb{T}$ and $\sup \emptyset = \inf \mathbb{T}$.

If $\sigma(t) > t$, we say that $t$ is right-scattered. Otherwise, $t$ is called right-dense. Analogously, if $\rho(t) < t$, then $t$ is called left-scattered whereas if $\rho(t) = t$, then $t$ is left-dense.

We also define the graininess function $\mu : \mathbb{T} \rightarrow \mathbb{R}^+$ and the backward graininess function $\nu : \mathbb{T} \rightarrow \mathbb{R}^+$, respectively, by

$$
\mu(t) = \sigma(t) - t \quad \text{and} \quad \nu(t) = t - \rho(t).
$$

**Definition 2.1.** A function $f : \mathbb{T} \rightarrow \mathbb{R}$ is called rd-continuous if it is regulated on $\mathbb{T}$ and continuous at right-dense points of $\mathbb{T}$. If the function $f : \mathbb{T} \rightarrow \mathbb{R}$ is continuous at each right-dense point and each left-dense point, then the function $f$ is said to be continuous on $\mathbb{T}$. We denote the class of all rd-continuous functions $f : \mathbb{T} \rightarrow \mathbb{R}$ by $C_{rd} = C_{rd}(\mathbb{T}) = C_{rd}(\mathbb{T}, \mathbb{R})$.

Given a pair of numbers $a, b \in \mathbb{T}$, the symbol $[a, b]_\mathbb{T}$ will be used to denote a closed interval in $\mathbb{T}$, that is, $[a, b]_\mathbb{T} = \{t \in \mathbb{T}; \ a \leq t \leq b\}$. On the other hand, $[a, b]$ is the usual closed interval on the real line, that is, $[a, b] = \{t \in \mathbb{R}; \ a \leq t \leq b\}$.

We define the set $\mathbb{T}^k$ which is derived from $\mathbb{T}$ as follows: If $\mathbb{T}$ has a left-scattered maximum $m$, then $\mathbb{T}^k = \mathbb{T} - \{m\}$. Otherwise, $\mathbb{T}^k = \mathbb{T}$.

**Definition 2.2.** For $y : \mathbb{T} \rightarrow \mathbb{R}$ and $t \in \mathbb{T}^k$, we define the delta-derivative of $y$ to be the number (if it exists) with the following property: given $\varepsilon > 0$, there exists a neighborhood $U$ of $t$ such that

$$
|y(\sigma(t)) - y(t) - y^\Delta(t)[\sigma(t) - s]| < \varepsilon|\sigma(t) - s|,
$$

for all $s \in U$.

Similarly, we can define the nabla-derivative of the function $y : \mathbb{T} \rightarrow \mathbb{R}$. For details, see [11] and [12].

**Definition 2.3.** A partition of $[a, b]_\mathbb{T}$ is a finite sequence of points

$$
\{t_0, t_1, \ldots, t_m\} \subset [a, b]_\mathbb{T}, \quad a = t_0 < t_1 < \ldots < t_m = b.
$$
Given such a partition, we put \( \Delta t_i = t_i - t_{i-1} \). A tagged partition consists of a partition and a sequence of tags \( \{\xi_1, \ldots, \xi_m\} \) such that \( \xi_i \in [t_{i-1}, t_i) \) for every \( i \in \{1, \ldots, m\} \). The set of all tagged partitions of \([a, b]\) will be denoted by the symbol \( D(a, b) \).

If \( \delta > 0 \), then \( D_\delta(a, b) \) denotes the set of all tagged partitions of \([a, b]\) such that for every \( i \in \{1, \ldots, m\} \), either \( \Delta t_i \leq \delta \), or \( \Delta t_i > \delta \) and \( \sigma(t_{i-1}) = t_i \). Note that in the last case, the only way to choose a tag in \([t_{i-1}, t_i)\) is to take \( \xi_i = t_{i-1} \).

In the sequel, we present the definition of Riemann \( \Delta \)-integrals. See [11] and [12], for instance.

**Definition 2.4.** We say that \( f \) is Riemann \( \Delta \)-integrable on \([a, b]\), if there exists a number \( I \) with the following property: for every \( \varepsilon > 0 \), there exists \( \delta > 0 \) such that

\[
\left| \sum_i f(\xi_i)(t_i - t_{i-1}) - I \right| < \varepsilon,
\]

for every \( P \in D_\delta(a, b) \) independently of \( \xi_i \in [t_{i-1}, t_i) \) for \( 1 \leq i \leq n \). It is clear that such a number \( I \) is unique and is the Riemann \( \Delta \)-integral of \( f \) from \( a \) to \( b \).

Similarly, we can define the Riemann \( \nabla \)-integrable functions on \([a, b]\). See [11] and [12], for instance.

In what follows, we present a concept of regressive functions.

**Definition 2.5.** We say that a function \( p : \mathbb{T} \to \mathbb{R} \) is regressive provided

\[
1 + \mu(t)p(t) \neq 0, \quad \text{for all} \quad t \in \mathbb{T}^k
\]

holds. The set of all regressive and rd-continuous functions will be denoted by \( \mathcal{R} = \mathcal{R}(\mathbb{T}) = \mathcal{R}(\mathbb{T}, \mathbb{R}) \).

Suppose that \( p, q \in \mathcal{R} \), then we define \( p \oplus q \) and \( \ominus p \) as follows:

\[
(p \oplus q)(t) := p(t) + q(t) + \mu(t)p(t)q(t), \quad \text{for all} \quad t \in \mathbb{T}^k
\]

and

\[
(\ominus p)(t) := \frac{-p(t)}{1 + \mu(t)p(t)}, \quad \text{for all} \quad t \in \mathbb{T}^k.
\]

It is clear that \( (\mathcal{R}, \oplus) \) is an Abelian group. (See, for instance, [11]). In the sequel, we define the generalized exponential function \( e_p(t, s) \).

**Definition 2.6.** If \( p \in \mathcal{R} \), then we define the generalized exponential function by

\[
e_p(t, s) = \exp \left( \int_s^t \xi_{\mu(\tau)}(p(\tau)) \Delta \tau \right) \quad \text{for} \quad s, t \in \mathbb{T},
\]

where the cylinder transformation \( \xi_h : \mathbb{C}_h \to \mathbb{Z}_h \) is given by

\[
\xi_h(z) = \frac{1}{h} \log(1 + zh),
\]

where \( \log \) is the principal logarithm function. For \( h = 0 \), we define \( \xi_0(z) = z \) for all \( z \in \mathbb{C} \).

In what follows, we present some definitions about matrix-valued functions on time scales.
Definition 2.7. Let $A$ be an $m \times n$ matrix-valued function on $\mathbb{T}$. We say that $A$ is \textit{rd-continuous} on $\mathbb{T}$ if each entry of $A$ is rd-continuous on $\mathbb{T}$. We denote the class of all rd-continuous $m \times n$ matrix-valued function on $\mathbb{T}$ by $\mathcal{C}_{rd} = \mathcal{C}_{rd}(\mathbb{T}) = \mathcal{C}_{rd}(\mathbb{T}, \mathbb{R}^{m \times n})$.

We say that $A$ is \textit{delta-differentiable} at $\mathbb{T}$ if each entry of $A$ is delta-differentiable on $\mathbb{T}$. And in this case, we have

$$A^\sigma(t) = A(t) + \mu(t)A^\Delta(t).$$

Definition 2.8. A $m \times n$ matrix-valued function $A$ on a time scale $\mathbb{T}$ is called \textit{regressive} (with respect to $\mathbb{T}$) provided

$$I + \mu(t)A(t) \text{ is invertible for all } t \in \mathbb{T}^k,$$

and the class of all such regressive rd-continuous is denoted by $\mathcal{R} = \mathcal{R}(\mathbb{T}) = \mathcal{R}(\mathbb{T}, \mathbb{R}^{m \times n})$.

Assume $A$ and $B$ are regressive $n \times n$ matrix-valued functions on $\mathbb{T}$. Then, we define $A \oplus B$ by

$$(A \oplus B)(t) = A(t) + B(t) + \mu(t)A(t)B(t), \quad \forall t \in \mathbb{T}^k,$$

and we define $\ominus A$ by

$$(\ominus A)(t) = -[I + \mu(t)A(t)]^{-1}A(t), \quad \forall t \in \mathbb{T}^k.$$  

It is clear that $(\mathcal{R}(\mathbb{T}, \mathbb{R}^{n \times n}), \oplus)$ is a group. For more details, see [11].

We proceed giving the definition of matrix exponential function found in [11].

Definition 2.9. (Matrix Exponential Function) Let $t_0 \in \mathbb{T}$ and assume that $A \in \mathcal{R}$ is an $n \times n$ matrix valued function. The unique matrix-valued solution of the IVP

$$Y^\Delta(t) = A(t)Y(t), \quad Y(t_0) = I,$$

where $I$ denotes as usual the $n \times n$-identity matrix, is called the \textit{matrix exponential function} at $t_0$ and it is denoted by $e_A(\cdot, t_0)$.

In the sequel, we enunciate a result which describes the properties of matrix exponential function. It can be found in [11], Theorem 5.21.

Theorem 2.10. If $A, B \in \mathcal{R}$ are matrix-valued functions on $\mathbb{T}$, then

(i) $e_0(t, s) \equiv I \iff A(t, s) \equiv I$;
(ii) $e_A(\sigma(t), s) = (I + \mu(t)A(t))e_A(t, s)$;
(iii) $e_A^{-1}(t, s) = e_A^*(s, t)$;
(iv) $e_A(t, s) = e_A^{-1}(s, t) = e_A^*(s, t)$;
(v) $e_A(t, s)e_A(s, r) = e_A(t, r)$;
(vi) $e_A(t, s)e_B(t, s) = e_{A \oplus B}(t, s)$ if $e_A(t, s)$ and $B(t)$ commute.

Using these notions, one can obtain the following result which is a Variation of Constants Formula which can be found in [11], Theorem 5.24.

Theorem 2.11 (Variation of Constants Formula). Let $A \in \mathcal{R}$ be an $n \times n$ matrix-valued function on $\mathbb{T}$ and suppose that $f : \mathbb{T} \to \mathbb{R}^n$ is rd-continuous. Let $t_0 \in \mathbb{T}$ and $y_0 \in \mathbb{R}^n$. Then the initial value problem

$$y^\Delta(t) = A(t)y(t) + f(t),$$
$$y(t_0) = y_0$$

(2.1)
has a unique solution \( y : \mathbb{T} \to \mathbb{R}^n \). Moreover, this solution is given by
\[
y(t) = e_A(t, t_0) y_0 + \int_{t_0}^{t} e_A(t, \sigma(\tau)) f(\tau) \Delta \tau.
\]

**Definition 2.12.** Let \( A(t) \) be \( n \times n \) rd-continuous matrix-valued function on \( \mathbb{T} \). We say that the linear system
\[
(2.2) \quad x^\Delta(t) = A(t)x(t)
\]
has an exponential dichotomy on \( \mathbb{T} \) if there exist positive constants \( K \) and \( \gamma \), projection \( P \), which commutes with \( X(t), t \in \mathbb{T} \), and fundamental solution matrix \( X(t) \) of (2.2) satisfying
\[
\begin{align*}
|X(t)PX^{-1}(s)| & \leq Ke^{-\gamma(s,t)}, \quad s, t \in \mathbb{T}, \quad t \geq s, \\
|X(t)(I-P)X^{-1}(s)| & \leq Ke^{-\gamma(s,t)}, \quad s, t \in \mathbb{T}, \quad t \leq s.
\end{align*}
\]

The following result will be essential to our purposes. For a proof of this result, see [11], Theorem 2.39.

**Theorem 2.13.** If \( p \in \mathcal{R} \) and \( a, b, c \in \mathbb{T} \), then
\[
[e_p(c, \cdot)]^\Delta = -p[e_p(c, \cdot)]^\sigma
\]
and
\[
\int_a^b p(t)e_p(c, \sigma(t)) \Delta t = e_p(c, a) - e_p(c, b).
\]

The following result shows that \( e_{\ominus \alpha}(t, s) \), for \( \alpha > 0 \), \( t > s \), is a bounded function. The proof is inspired in [41], Lemma 5.1.

**Theorem 2.14.** If \( \alpha > 0 \), then \( e_{\ominus \alpha}(t, s) \leq 1 \) for \( t, s \in \mathbb{T} \) such that \( t > s \).

**Proof.** First, we suppose \( \mu(t) = 0 \), then
\[
e_{\ominus \alpha}(t, s) = \exp \left( \int_s^t \xi_0(\ominus \alpha) \Delta \tau \right),
\]
for every \( s, t \in \mathbb{T} \). Then,
\[
e_{\ominus \alpha}(t, s) = \exp \left( \int_s^t \ominus \alpha \Delta \tau \right) = \exp \left( \int_s^t -\alpha \frac{1}{1 + \mu(\tau) \alpha} \Delta \tau \right) = \exp (-\alpha(t - s)),
\]
using the fact that \( \mu(\tau) = 0 \). Since \( t > s \), we obtain
\[
e_{\ominus \alpha}(t, s) = \exp (-\alpha(t - s)) \leq 1.
\]

Now, let us consider \( \mu(t) > 0 \), then
\[
1 + \mu(t) \ominus \alpha = 1 + \mu(t) \frac{-\alpha}{1 + \mu(t) \alpha} = \frac{1 + \mu(t) \alpha - \mu(t) \alpha}{1 + \mu(t) \alpha} = \frac{1}{1 + \mu(t) \alpha} < 1.
\]

Thus, \( \ominus \alpha \in \mathcal{R} \) and it is easy to see that
\[
\log(1 + \mu(t) \ominus \alpha) \in \mathbb{R}
\]
for all \( t \in \mathbb{T} \). Then, it follows
\[
\xi_{\mu(t)}(\ominus \alpha) = \frac{\log(1 + \mu(t) \ominus \alpha)}{\mu(t)} < 0,
\]
which implies that  
\[ e_{\ominus \alpha}(t, s) = \exp \left( \int_s^t \xi_{\mu(t)}(\ominus \alpha) \right) < 1, \]
for every \( t, s \in \mathbb{T} \) such that \( t > s \).

The next result describes the solution of (2.1). It can be found in [40], Lemma 2.13.

**Theorem 2.15.** If the linear system (2.2) admits exponential dichotomy, then the system (2.1) has a bounded solution \( x(t) \) as follows:
\[
x(t) = \int_{-\infty}^t X(t) P X^{-1}(s) f(s) \Delta s - \int_t^{+\infty} X(t)(I - P) X^{-1}(s) f(s) \Delta s,
\]
where \( X(t) \) is the fundamental solution matrix of (2.2).

### 3. Almost automorphic functions on time scales

In this section, we introduce almost automorphic functions on time scales and present their properties.

We start by introducing a definition of an invariant under translations time scale.

**Definition 3.1.** A time scale \( \mathbb{T} \) is called **invariant under translations** if
\[
\Pi := \{ \tau \in \mathbb{R} : t \pm \tau \in \mathbb{T}, \ \forall t \in \mathbb{T} \} \neq \{0\}.
\]

We say that the graininess function \( \mu : \mathbb{T} \to \mathbb{R}_+ \) is an **almost automorphic function** if for every sequence \((\alpha'_n)\) on \( \Pi \), there exists a subsequence \((\alpha_n) \subset (\alpha'_n)\) such that
\[
\lim_{n \to \infty} \mu(t + \alpha_n) = \bar{\mu}(t),
\]
for every \( t \in \mathbb{T} \) and
\[
\lim_{n \to \infty} \bar{\mu}(t - \alpha_n) = \mu(t),
\]
for every \( t \in \mathbb{T} \).

Combining the Theorems 1.9, 1.10 and 1.11 from [21], we obtain the following characterization of almost periodic functions \( f : \mathbb{R} \to \mathbb{R} \).

**Theorem 3.2.** The function \( f : \mathbb{R} \to \mathbb{R} \) is almost periodic, if and only if, from any sequence of the form \( \{f(x + \alpha_n)\} \), where \((\alpha_n)\) is a sequence of real numbers, one can extract a subsequence converging uniformly on the real line.

A carefully examination of the proofs of the Theorems 1.9, 1.10 and 1.11 from [21] reveals that the result above remains true for a general time scale. More precisely, we obtain the next result.

**Theorem 3.3.** Let \( \mathbb{T} \) be an invariant under translations time scale, then the function \( f : \mathbb{T} \to \mathbb{R} \) is almost periodic, if and only if, from any sequence of the form \( \{f(x + \alpha_n)\} \), where \((\alpha_n)\) is a sequence on \( \Pi \), one can extract a subsequence converging uniformly on \( \mathbb{T} \).

Therefore, using this fact and the definition of invariant under translations time scales, we get the following result.
Theorem 3.4. If $T$ is an invariant under translations time scale, then the graininess function $\mu : T \to \mathbb{R}_+$ is an almost periodic function.

Proof. If the time scale $T$ is invariant under translation, then the equation (3.1) is satisfied. Then, let us consider two cases: if all the points in $T$ are right-dense (or/and left-dense) and otherwise.

Let us consider that all the points in $T$ are right-dense. (Notice that the cases of all points in $T$ are left-dense or even are right-dense and left-dense at the same time follow similarly. Thus, we will prove only this case). From this fact and since $T$ is invariant under translation, we obtain that $T = \mathbb{R}$, because the condition (3.1) must be satisfied. Therefore, in this case, it follows that $\mu(t) = 0$ for every $t \in T$ and the almost periodicity of the graininess function follows immediately.

Now, let us suppose that $T$ has at least one point which is not right-dense (or left-dense), then in this case, it makes sense to consider $\min\{|\tau| : \tau \in \Pi\}$, which is clearly finite, since $\tau \in \mathbb{R}$. Thus, denote $K := \min\{|\tau| : \tau \in \Pi\}$.

Then, by the definition of forward jump operator $\sigma : T \to T$, we have
$$\sigma(t) \leq t + K,$$
which implies that $\mu(t) \leq K$, for every $t \in T$.

Given a sequence $(\alpha_n) \in \Pi$, define $\mu_n(t) := \mu(t + \alpha_n)$. Obviously, by the properties of an invariant under translations time scale, we have $\mu_n : T \to \mathbb{R}_+$. Therefore, since the function $\mu_n$ takes value on $\mathbb{R}_+$ and is bounded ($0 \leq \mu_n(t) \leq K$), we obtain by Bolzano-Weierstrass Theorem that $\mu_n$ possesses a subsequence which converges uniformly.

Thus, by Theorem 3.3 and using the fact that $\{\mu(t + \alpha_n)\}$ possesses a subsequence which converges uniformly, we obtain that $\mu$ is an almost periodic function. □

Using the fact that every almost periodic function is almost automorphic, we obtain as an immediate consequence of the previous theorem the following result.

Corollary 3.5. If $T$ is an invariant under translations time scales, then the graininess function $\mu : T \to \mathbb{R}_+$ is almost automorphic.

Remark 3.6. We point out that in the paper [40], the authors use the same definition of an invariant under translation time scale presented here to define an almost periodic time scale.

However, by Corollary 3.5, one can see that this concept is more general, since it can be also applied to study almost automorphic functions. Therefore, we rewritten the definition presented in [40] and called the time scale which satisfies the property (3.1) as invariant under translations.

If $\tau_1, \tau_2 \in \Pi$, then $\tau_1 \pm \tau_2 \in \Pi$ and $T$ is an invariant under translations time scale, then $\inf T = -\infty$ and $\sup T = +\infty$.

In what follows, we give some interesting examples of invariant under translations time scales $T$.

Example 3.7. The time scales $T = \mathbb{Z}$ and $T = \mathbb{R}$ are clearly invariant under translations.

Example 3.8. Notice that $T = h\mathbb{Z}$, for $h \in \mathbb{Z}$ and $T = \frac{1}{n}\mathbb{Z}$, $n \in \mathbb{N}_0 = \mathbb{N} \setminus \{0\}$ are invariant under translations time scales.
Example 3.9. Consider the time scale

$$\mathbb{P}_{a,b} = \bigcup_{k=-\infty}^{\infty} [k(a + b), k(a + b) + a]$$

then

$$\sigma(t) = \begin{cases} 
  t, & \text{if } t \in \bigcup_{k=-\infty}^{\infty} [k(a + b), k(a + b) + a] \\
  t + b, & \text{if } t \in \bigcup_{k=-\infty}^{\infty} \{k(a + b) + a\}
\end{cases}$$

and

$$\mu(t) = \begin{cases} 
  0, & \text{if } t \in \bigcup_{k=-\infty}^{\infty} [k(a + b), k(a + b) + a] \\
  \cos t, & \text{if } t \in \bigcup_{k=-\infty}^{\infty} \{k(a + b) + a\}
\end{cases}$$

By the definition, it follows that \(\mathbb{P}_{a,b}\) is an invariant under translation time scale.

Considering \(a = 1\) and \(b = 1\) in the Example 3.9, we obtain that \(\mathbb{P}_{1,1}\) describes the population of certain species which its life span is one unit of time. In other words, just before the species dies out, eggs are laid which are hatched one unit of time later. For this specific case, see [19].

The following two examples bring more complex time scales. They might describe a population of certain species which its life span behaves the same way as a cosine and sin function, respectively.

Example 3.10. Let \(0 < a < \frac{\pi}{2}\) and consider the time scale

$$\mathbb{P}_{a,\cos a} = \bigcup_{k=-\infty}^{\infty} [k(a + \cos a), k(a + \cos a) + a]$$

then

$$\sigma(t) = \begin{cases} 
  t, & \text{if } t \in \bigcup_{k=-\infty}^{\infty} [k(a + \cos a), k(a + \cos a) + a] \\
  t + \cos t, & \text{if } t \in \bigcup_{k=-\infty}^{\infty} \{k(a + \cos a) + a\}
\end{cases}$$

and

$$\mu(t) = \begin{cases} 
  0, & \text{if } t \in \bigcup_{k=-\infty}^{\infty} [k(a + \cos a), k(a + \cos a) + a] \\
  \cos t, & \text{if } t \in \bigcup_{k=-\infty}^{\infty} \{k(a + \cos a) + a\}
\end{cases}$$

It is clear that \(\mathbb{P}_{a,\cos a}\) is an invariant under translations time scale.
Example 3.11. Let $\frac{\pi}{2} < a < \pi$ and consider the time scale

$$\mathbb{P}_{a,\sin a} = \bigcup_{k=-\infty}^{\infty} [k(a + \sin a), k(a + \sin a) + a]$$

then

$$\sigma(t) = \begin{cases} 
    t, & \text{if } t \in \bigcup_{k=-\infty}^{\infty} [k(a + \sin a), k(a + \sin a) + a] \\
    t + \sin t, & \text{if } t \in \bigcup_{k=-\infty}^{\infty} \{k(a + \sin a) + a\}
\end{cases}$$

and

$$\mu(t) = \begin{cases} 
    0, & \text{if } t \in \bigcup_{k=-\infty}^{\infty} [k(a + \sin a), k(a + \sin a) + a] \\
    \sin t, & \text{if } t \in \bigcup_{k=-\infty}^{\infty} \{k(a + \sin a) + a\}
\end{cases}$$

Clearly, $\mathbb{P}_{a,\sin a}$ is an invariant under translations time scale.

In the sequel, we present some time scales which are not invariant under translations.

Example 3.12. Clearly, $\mathbb{T} = q\mathbb{Z} \cup \{0\}$, $q > 1$, is not invariant under translations, since $\mathbb{T}$ does not satisfy the condition (3.1). Note that $\mu(t) = (q - 1)t$.

Example 3.13. Every compact interval $\mathbb{T} = [a, b]$, $a, b \in \mathbb{R}$, is not invariant under translations.

Example 3.14. The time scales $\mathbb{T} = \mathbb{N}_{0}^2$ and $\mathbb{T} = 2\mathbb{N}$ are not invariant under translations. Here $\mu(t) = 2\sqrt{t} + 1$ and $\mu(t) = t$ respectively.

Now, we introduce the definition of an almost automorphic function on time scales.

**Definition 3.15.** Let $X$ be (real or complex) Banach space and $\mathbb{T}$ be an invariant under translation time scale. Then, an rd-continuous function $f : \mathbb{T} \to X$ is called almost automorphic on $\mathbb{T}$ if for every sequence $(\alpha_n') \in \Pi$, there exists a subsequence $(\alpha_n) \subset (\alpha_n')$ such that

$$\lim_{n \to \infty} f(t + \alpha_n) = \bar{f}(t)$$

is well defined for each $t \in \mathbb{T}$ and

$$\lim_{n \to \infty} \bar{f}(t - \alpha_n) = f(t),$$

for every $t \in \mathbb{T}$.

We denote the space of all almost automorphic function on time scales $f : \mathbb{T} \to X$ by $AA_{\mathbb{T}}(X)$.

In what follows, we present some properties concerning almost automorphic function on time scale $\mathbb{T}$. The proof is inspired in Theorems 2.1.3 and 2.1.4, from [32].
Theorem 3.16. Let $\mathbb{T}$ be an invariant under translations time scale and suppose the rd-continuous functions $f, g : \mathbb{T} \to X$ are almost automorphic on time scales, then the following assertions hold.

(i) $f + g$ is almost automorphic function on time scales;
(ii) $cf$ is almost automorphic function on time scales for every scalar $c$;
(iii) For each $l \in \mathbb{T}$, the function $f_l : \mathbb{T} \to X$ defined by $f_l(t) := f(l + t)$ is almost automorphic on time scales.
(iv) The function $\hat{f} : \mathbb{T} \to X$ defined by $\hat{f}(t) := f(-t)$ is almost automorphic on time scales;
(v) $\sup_{t \in \mathbb{T}} \|f(t)\| < \infty$, that is, $f$ is a bounded function;
(vi) $\sup_{t \in \mathbb{T}} \|\tilde{f}(t)\| \leq \sup_{t \in \mathbb{T}} \|f(t)\|$, where

$$
\lim_{n \to \infty} f(t + \alpha_n) = \hat{f}(t) \quad \text{and} \quad \lim_{n \to \infty} \hat{f}(t - \alpha_n) = f(t).
$$

Proof. Let $f, g : \mathbb{T} \to X$ be almost automorphic functions on time scales. Then, for every sequence $(\alpha'_n) \subseteq \Pi$, there exists a subsequence $(\alpha_n) \subseteq (\alpha'_n)$ such that

$$
\lim_{n \to \infty} f(t + \alpha_n) = \hat{f}(t) \quad \text{and} \quad \lim_{n \to \infty} g(t + \alpha_n) = \tilde{g}(t)
$$

is well defined for each $t \in \mathbb{T}$ and

$$
\lim_{n \to \infty} \hat{f}(t - \alpha_n) = f(t) \quad \text{and} \quad \lim_{n \to \infty} \tilde{g}(t - \alpha_n) = g(t),
$$

for every $t \in \mathbb{T}$. Thus, we obtain

$$
\lim_{n \to \infty} (f + g)(t + \alpha_n) := \hat{f}(t) + \tilde{g}(t)
$$

is well defined for each $t \in \mathbb{T}$ and

$$
\lim_{n \to \infty} (\hat{f} + \tilde{g})(t - \alpha_n) = f(t) + g(t),
$$

for every $t \in \mathbb{T}$. Thus, item (i) follows.

Since $f$ is almost automorphic function on time scales, then for every sequence $(\alpha'_n) \subseteq \Pi$, there exists a subsequence $(\alpha_n) \subseteq (\alpha'_n)$ such that

$$
\lim_{n \to \infty} (cf)(t + \alpha_n) = \lim_{n \to \infty} cf(t + \alpha_n) = c\hat{f}(t) = (cf)(t)
$$

is well defined for each $t \in \mathbb{T}$ and

$$
\lim_{n \to \infty} (c\hat{f})(t - \alpha_n) = \lim_{n \to \infty} c\hat{f}(t - \alpha_n) = cf(t) = (cf)(t),
$$

for every $t \in \mathbb{T}$, which proves item (ii).

The proofs of item (iii) and (iv) follow using similar argument as before. Thus, we omit them here.

Let us prove item (v). Let $t_0 \in \mathbb{T}$ and suppose that $\sup_{k \in \mathbb{T}} \|f(k)\| = \infty$, then there exists a sequence $(\alpha'_n) \subseteq \Pi$ such that

$$
\lim_{n \to \infty} \|f(t_0 + \alpha'_n)\| = \infty.
$$
Since $f$ is almost automorphic, there exists a subsequence $(\alpha_n) \subset (\alpha'_n)$ such that
\[
\lim_{n \to \infty} f(t_0 + \alpha_n) = \bar{f}(t_0),
\]
and using the continuity of norm function, we get
\[
\lim_{n \to \infty} \| f(t_0 + \alpha_n) \| = \| \bar{f}(t_0) \| < \infty,
\]
which contradicts the fact that $\lim_{n \to \infty} \| f(t_0 + \alpha'_n) \| = \infty$.

Finally, let us prove item (vi). Let $(\alpha'_n)$ be a sequence on $\Pi$, then there exists a subsequence $(\alpha_n) \subset (\alpha'_n)$ such that
\[
\| \bar{f}(t) \| = \| \lim_{n \to \infty} f(t + \alpha_n) \| = \lim_{n \to \infty} \| f(t + \alpha_n) \| \leq \sup_{t \in \mathbb{T}} \| f(t) \|,
\]
which implies that
\[
\begin{equation}
\sup_{t \in \mathbb{T}} \| \bar{f}(t) \| \leq \sup_{t \in \mathbb{T}} \| f(t) \|.
\end{equation}
\]

On the other hand, we have
\[
\| f(t) \| = \| \lim_{n \to \infty} \bar{f}(t + \alpha_n) \| \leq \sup_{t \in \mathbb{T}} \| \bar{f}(t) \|,
\]
then
\[
\begin{equation}
\sup_{t \in \mathbb{T}} \| f(t) \| \leq \sup_{t \in \mathbb{T}} \| \bar{f}(t) \|.
\end{equation}
\]
Combining (3.4) and (3.5), we obtain
\[
\sup_{t \in \mathbb{T}} \| f(t) \| = \sup_{t \in \mathbb{T}} \| \bar{f}(t) \|,
\]
and the result follows as well. \qed

The next result generalizes item (ii) from Theorem 3.16. The proof is inspired in Theorem 2.7, from [3].

**Theorem 3.17.** Let $\mathbb{T}$ be invariant under translations and the functions $f, u : \mathbb{T} \to X$ be almost automorphic on time scales, then the function $uf : \mathbb{T} \to X$ defined by $(uf)(t) = u(t)f(t)$ is almost automorphic on time scales.

**Proof.** Let $(\alpha'_n)$ be a sequence on $\Pi$, then there exists a subsequence $(\alpha''_n) \subset (\alpha'_n)$ such that
\[
\lim_{n \to \infty} u(t + \alpha''_n) = \bar{u}(t)
\]
is well defined for each $t \in \mathbb{T}$ and $\lim_{n \to \infty} \bar{u}(t - \alpha''_n) = u(t)$ for each $t \in \mathbb{T}$. Since $f$ is almost automorphic, there exists a subsequence $(\alpha_n) \subset (\alpha''_n)$ such that
\[
\lim_{n \to \infty} f(t + \alpha_n) = \bar{f}(t)
\]
is well defined for each $t \in \mathbb{T}$ and $\lim_{n \to \infty} \bar{f}(t - \alpha_n) = f(t)$ for each $t \in \mathbb{T}$. Thus,
\[
\| u(t + \alpha_n)f(t + \alpha_n) - \bar{u}(t)\bar{f}(t) \| \leq \| u(t + \alpha_n)(f(t + \alpha_n) - \bar{f}(t)) \|
\]
\[
+ \| (u(t + \alpha_n) - \bar{u}(t))\bar{f}(t) \|
\]
\[
< \varepsilon,
\]
for $n$ sufficiently large. Therefore,
\[
\lim_{n \to \infty} u(t + \alpha_n)f(t + \alpha_n) = \bar{u}(t)\bar{f}(t),
\]
for every $t \in \mathbb{T}$. Analogously, we can prove that \( \lim_{n \to \infty} \bar{u}(t - \alpha_n) \bar{f}(t - \alpha_n) = u(t)f(t) \). Thus, we obtain that $uf$ is an almost automorphic function on time scales. \( \square \)

In the sequel, we present a result which ensures that $AA_{\mathbb{T}}(X)$ is a Banach space with the norm described in item (v) from Theorem 3.16. The proof is inspired in [32], Theorem 2.1.10.

**Theorem 3.18.** Let $\mathbb{T}$ be an invariant under translations time scale and $(f_n)$ be a sequence of almost automorphic functions such that $\lim_{n \to \infty} f_n(t) = f(t)$ converges uniformly for each $t \in \mathbb{T}$. Then, $f$ is an almost automorphic function.

**Proof.** Let $(\alpha'_n)$ be a sequence on $\Pi$. Since $f_1 \in AA_{\mathbb{T}}(X)$, then there exists a subsequence $(\alpha_n^1) \subset (\alpha'_n)$ such that

\[
\lim_{n \to \infty} f_1(t + \alpha_n^1) := \tilde{f}_1(t)
\]

is well-defined for every $t \in \mathbb{T}$ and

\[
\lim_{n \to \infty} \tilde{f}_1(t - \alpha_n^1) = f_1(t),
\]

for every $t \in \mathbb{T}$. Since $f_2 \in AA_{\mathbb{T}}(X)$, then there exists a subsequence $(\alpha_n^2) \subset (\alpha_n^1)$ such that

\[
\lim_{n \to \infty} f_2(t + \alpha_n^2) = \tilde{f}_2(t)
\]

is well-defined for every $t \in \mathbb{T}$ and

\[
\lim_{n \to \infty} \tilde{f}_2(t - \alpha_n^2) = f_2(t),
\]

for every $t \in \mathbb{T}$. Thus, by the diagonal procedure, we can construct a subsequence $(\alpha_n) \subset (\alpha_n')$ such that

\[
\lim_{n \to \infty} f_i(t + \alpha_n) = \tilde{f}_i(t),
\]

for each $t \in \mathbb{T}$ and for all $i = 1, 2, 3, \ldots$. Notice that

\[
\|\tilde{f}_i(t) - \tilde{f}_j(t)\| \leq \|\tilde{f}_i(t) - f_i(t + \alpha_n)\| + \|f_i(t + \alpha_n) - f_j(t + \alpha_n)\| + \|f_j(t + \alpha_n) - \tilde{f}_j(\alpha_n)\|. \tag{3.6}
\]

Let $\varepsilon > 0$, then by the uniform convergence of $(f_n)$, we can find $N \in \mathbb{N}$ sufficiently large such that for all $i, j > N$, we obtain

\[
\|f_i(t + s_n) - f_j(t + s_n)\| < \varepsilon, \tag{3.8}
\]

for all $t \in \mathbb{T}$ and all $n = 1, 2, \ldots$.

Therefore, taking $i, j$ sufficiently large in (3.7) and using (3.8) and the limit (3.6), we obtain that $(\tilde{f}_i(t))$ is a Cauchy sequence. Since $X$ is a Banach space, then $(\tilde{f}_i(t))$ is a sequence which converges pointwisely on $X$. Let $\tilde{f}(t)$ be the limit of $(\tilde{f}_i(t))$, then for each $i = 1, 2, 3, \ldots$, we have

\[
\|f(t + \alpha_n) - \tilde{f}(t)\| \leq \|f(t + \alpha_n) - f_i(t + \alpha_n)\| + \|f_i(t + \alpha_n) - \tilde{f}_i(t)\| + \|\tilde{f}_i(t) - \tilde{f}(t)\|. \tag{3.9}
\]
Then, for $i$ sufficiently large, by (3.9) and using the almost automorphicity of $f_i$ and the convergence of the functions $f_i$ and $\bar{f}_i$, we obtain

$$\lim_{n \to \infty} f(t + \alpha_n) = \bar{f}(t),$$

for each $t \in \mathbb{T}$. Analogously, one can prove that

$$\lim_{n \to \infty} \bar{f}(t - \alpha_n) = f(t),$$

for every $t \in \mathbb{T}$ and we get the desired result. \hfill \Box

In what follows, we present a result which brings a property concerning composition of almost automorphic function on time scales and a continuous function. The proof is inspired in [3], Theorem 2.5.

**Theorem 3.19.** Let $\mathbb{T}$ be invariant under translations and let $X, Y$ be Banach spaces. Suppose $f : \mathbb{T} \to X$ is an almost automorphic function on time scales and $\phi : X \to Y$ is a continuous function, then the composite function $\phi \circ f : \mathbb{T} \to Y$ is an almost automorphic function on time scales.

**Proof.** Since $f \in AA_\mathbb{T}(X)$, for every sequence $(\alpha'_n)$ on $\Pi$, there exists a subsequence $(\alpha_n) \subset (\alpha'_n)$ such that $\lim_{n \to \infty} f(t + \alpha_n) = \bar{f}(t)$ is well defined for every $t \in \mathbb{T}$ and $\lim_{n \to \infty} \bar{f}(t - \alpha_n) = f(t)$ for each $t \in \mathbb{T}$.

By the continuity of function $\phi$, it follows that

$$\lim_{n \to \infty} \phi(f(t + \alpha_n)) = \phi(\lim_{n \to \infty} f(t + \alpha_n)) = (\phi \circ \bar{f})(t).$$

Similarly, we have

$$\lim_{n \to \infty} \phi(\bar{f}(t - \alpha_n)) = \phi(\lim_{n \to \infty} \bar{f}(t - \alpha_n)) = (\phi \circ f)(t)$$

for each $t \in \mathbb{T}$. Thus, $\phi \circ f \in AA_\mathbb{T}(Y)$. \hfill \Box

Now, we present the definition of an almost automorphic function on time scales depending on one parameter. This definition is useful for applications to nonlinear dynamic equations.

**Definition 3.20.** Let $X$ be a (real or complex) Banach space and $\mathbb{T}$ be an invariant under translations time scale. Then, an rd-continuous function $f : \mathbb{T} \times X \to X$ is called almost automorphic on $t \in \mathbb{T}$ for each $x \in X$, if for every sequence $(\alpha'_n) \in \Pi$, there exists a subsequence $(\alpha_n) \subset (\alpha'_n)$ such that

$$\lim_{n \to \infty} f(t + \alpha_n, x) = \bar{f}(t, x)$$

is well defined for each $t \in \mathbb{T}$, $x \in X$ and

$$\lim_{n \to \infty} \bar{f}(t - \alpha_n, x) = f(t, x),$$

for every $t \in \mathbb{T}$ and $x \in X$.

In the sequel, we present a result concerning the properties of almost automorphic functions on time scales to respect the first variable. We omit the proof since it is similar to proof of Theorem 3.16.
**Theorem 3.21.** Let \( \mathbb{T} \) be invariant under translations and \( f, g : \mathbb{T} \times X \to X \) be almost automorphic functions on time scales in \( t \) for each \( x \) in \( X \), then the following assertions hold.

(i) \( f + g \) is almost automorphic function on time scales in \( t \) for each \( x \) in \( X \).
(ii) \( cf \) is almost automorphic function on time scales in \( t \) for each \( x \) in \( X \), where \( c \) is an arbitrary scalar.
(iii) \( \sup_{t \in \mathbb{T}} \| f(t, x) \| = M_x < \infty \), for each \( x \) in \( X \).
(iv) \( \sup_{t \in \mathbb{T}} \| \bar{f}(t, x) \| = N_x < \infty \), for each \( x \) in \( X \), where \( \bar{f} \) is the function in the Definition 3.20.

Now, we present a result which will be essential to prove the following one. The proof is inspired in Theorem 2.2.5 from [32].

**Theorem 3.22.** Let \( \mathbb{T} \) be invariant under translations and \( f : \mathbb{T} \times X \to X \) be almost automorphic function on time scales for each \( x \in X \) and if \( f \) is Lipschitzian in \( x \) uniformly in \( t \), then \( \bar{f} \) given by (3.10) and (3.11) satisfies the same Lipschitz condition in \( x \) uniformly in \( t \).

**Proof.** Let \( L > 0 \) be a Lipschitz constant for the function \( f \), that is, the following inequality
\[
\| f(t, x) - f(t, y) \| \leq L \| x - y \|
\]
holds for every \( x, y \in X \) uniformly in \( t \in \mathbb{T} \).

Let \( t \in \mathbb{T} \) be arbitrary and \( \varepsilon > 0 \) be given. Then, by the automorphicity of function \( f \) and the definition of \( \bar{f} \), for every any sequence \((\alpha_n') \in \Pi\), there exists a subsequence \((\alpha_n) \subset (\alpha_n')\) such that
\[
\| \bar{f}(t, x) - f(t + \alpha_n, x) \| \leq \frac{\varepsilon}{2} \quad \text{and} \quad \| \bar{f}(t, y) - f(t + \alpha_n, y) \| \leq \frac{\varepsilon}{2},
\]
for \( n \) sufficiently large.

Therefore, we obtain
\[
\| \bar{f}(t, x) - \bar{f}(t, y) \| \leq \| \bar{f}(t, x) - f(t + \alpha_n, x) \| + \| \bar{f}(t, y) - f(t + \alpha_n, y) \| + \| f(t + \alpha_n, x) - f(t + \alpha_n, y) \| \\
\leq \varepsilon + L \| x - y \|.
\]

Since \( \varepsilon \) is arbitrary, we get
\[
\| \bar{f}(t, x) - \bar{f}(t, y) \| \leq L \| x - y \|,
\]
for each \( x, y \in X \). \( \square \)

The next result will be fundamental to ensure the almost automorphicity of solutions of nonlinear dynamic equations. Our proof is inspired in Theorem 2.10 from [3].

**Theorem 3.23.** Let \( \mathbb{T} \) be an invariant under translations time scale and \( f : \mathbb{T} \times X \to X \) be an almost automorphic function on time scales in \( t \) for each \( x \) in \( X \) and satisfies Lipschitz condition in \( x \) uniformly in \( t \), that is
\[
\| f(t, x) - f(t, y) \| \leq L \| x - y \|,
\]
for all \( x, y \in X \). Suppose \( \phi : \mathbb{T} \to X \) is almost automorphic function on time scales, then the function \( U : \mathbb{T} \to X \) defined by \( U(t) = f(t, \phi(t)) \) is almost automorphic on time scales.

**Proof.** Since \( f, \phi \in AA_T(X) \), then for every sequence \((\alpha'_n)\) in \( \Pi \), there exists a subsequence \((\alpha_n) \subset (\alpha'_n)\) such that \( \lim_{n \to \infty} f(t + \alpha_n, x) = \bar{f}(t, x) \) for all \( t \in \mathbb{T} \), \( x \in X \) and \( \lim_{n \to \infty} \bar{f}(t - \alpha_n, x) = f(t, x) \) for all \( t \in \mathbb{T} \) and \( x \in X \). Also, we have

\[
\lim_{n \to \infty} \phi(t + \alpha_n) = \bar{\phi}(t)
\]

is well-defined for each \( t \in \mathbb{T} \) and

\[
\lim_{n \to \infty} \bar{\phi}(t - \alpha_n) = \phi(t)
\]

for every \( t \in \mathbb{T} \). Since \( f \) satisfies the Lipschitz condition in \( t \) uniformly in \( k \), then

\[
\| f(t + \alpha_n, \phi(t + \alpha_n)) - \bar{f}(t, \bar{\phi}(t)) \| \leq \| f(t + \alpha_n, \phi(t + \alpha_n)) - f(t + \alpha_n, \bar{\phi}(t)) \| + \| f(t + \alpha_n, \bar{\phi}(t)) - \bar{f}(t, \bar{\phi}(t)) \|
\]

and

\[
\| f(t - \alpha_n, \bar{\phi}(t - \alpha_n)) - f(t, \phi(t)) \| \leq \| f(t - \alpha_n, \bar{\phi}(t - \alpha_n)) - f(t - \alpha_n, \phi(t)) \| + \| f(t - \alpha_n, \phi(t)) - f(t, \phi(t)) \|
\]

and

\[
\| f(t - \alpha_n, \phi(t - \alpha_n)) - f(t, \phi(t)) \| \leq \| f(t - \alpha_n, \phi(t - \alpha_n)) - f(t - \alpha_n, \phi(t)) \| + \| f(t - \alpha_n, \phi(t)) - f(t, \phi(t)) \|
\]

Notice that if \( f \) satisfies Lipschitz condition in \( x \) uniformly in \( t \), it is clear by Theorem 3.22 that \( \bar{f} \) also satisfies this condition in \( x \) uniformly in \( t \) for the same constant \( L > 0 \). Applying limit as \( n \to \infty \) to both inequalities above, we have the desired result. \( \square \)

## 4. Product integration on time scales

In this section, we present some basic concepts concerning product integration on time scales which will be essential to prove our main result. The main reference for this section is [45].

We start this section by presenting a notion of product \( \Delta \)-integral of a matrix function. For details, see [45].

Given a matrix function \( A : [a, b]_\mathbb{T} \to \mathbb{R}^{n \times n} \) and a tagged partition \( D \in D(a, b) \), we denote

\[
P(A, D) = \prod_{i=m}^{1} (I + A(\xi_i) \Delta t_i) = (I + A(\xi_m) \Delta t_m) \cdot (I + A(\xi_1) \Delta t_1).
\]

We point out that the order is important since matrix multiplication is usually not commutative.

Now, we present the concept of product \( \Delta \)-integrable matrix function. See [45].

**Definition 4.1.** A bounded matrix function \( A : [a, b]_\mathbb{T} \to \mathbb{R}^{n \times n} \) is called product \( \Delta \)-integrable if there exists a matrix \( P \in \mathbb{R}^{n \times n} \) with the property that for every \( \varepsilon > 0 \), there
exists a $\delta > 0$ such that $\|P(A, D) - P\| < \varepsilon$ for every $D \in D_\delta(a, b)$. The matrix $P$ is called the product $\Delta$-integral of $A$ over $[a, b]_T$ and we write
\[
\prod_a^b (I + A(t)\Delta t) = P.
\]

If $a = b$, then $\prod_a^a (I + A(t)\Delta t) = I$ for every matrix function $A : [a, b]_T \to \mathbb{R}^{n \times n}$.

Now, we present a result which will be essential to our purposes. It can be found in [45], Theorem 2.9.

**Theorem 4.2.** Let $A : [a, b]_T \to \mathbb{R}^{n \times n}$ and $t \in T$, $a \leq t \leq \sigma(t) \leq b$. Then
\[
\prod_t^\sigma (I + A(s)\Delta s) = I + A(t)\mu(t).
\]

The next result brings a property of Riemann $\Delta$-integrable function. It can be found in [45], Theorem 3.7.

**Theorem 4.3.** Every Riemann $\Delta$-integrable function is product $\Delta$-integrable.

We remind the reader that every rd-continuous function $f : [a, b]_T \to \mathbb{R}^n$ is Riemann $\Delta$-integrable (see [11] and [12]). Thus, we can replace the previous result by the following one.

**Theorem 4.4.** Every rd-continuous function is product $\Delta$-integrable.

In what follows, we state a property of product $\Delta$ integrals. See [45].

**Theorem 4.5.** If $A : [a, b]_T \to \mathbb{R}^{n \times n}$ is Riemann $\Delta$-integrable and $c \in [a, b]_T$, then
\[
\prod_a^c (I + A(t)\Delta t) = \prod_a^b (I + A(t)\Delta t) \cdot \prod_a^c (I + A(t)\Delta t).
\]

The next result ensures the continuity of the indefinite product $\Delta$-integral on $[a, b]_T$. See [45], Theorem 4.1.

**Theorem 4.6.** If $A : [a, b]_T \to \mathbb{R}^{n \times n}$ is Riemann $\Delta$-integrable, then the indefinite product $\Delta$-integral
\[
Y(t) = \prod_a^t (I + A(s)\Delta s), \quad t \in [a, b]_T,
\]
is continuous on $[a, b]_T$.

**Theorem 4.7** ([45], Theorem 5.5). If $A : [a, b]_T \to \mathbb{R}^{n \times n}$ is a regressive Riemann $\Delta$-integrable function, then $\prod_a^b (I + A(t)\Delta t)$ is a nonsingular matrix.

If $a < b$, we define $\prod_a^b (I + A(t)\Delta t) = \left(\prod_a^b (I + A(t)\Delta t)\right)^{-1}$ provided the right-hand side exists. See [45], Definition 5.6.

Finally, we present a result which will be fundamental to prove our main result. It can be found in [45], Theorem 5.7.
Theorem 4.8. If $A : \mathbb{T} \to \mathbb{R}^{n \times n}$ is a regressive rd-continuous function and $t_0 \in \mathbb{T}$, then the function

$$Y(t) = \prod_{t_0}^{t} (I + A(s)\Delta s), \quad t \in \mathbb{T},$$

represents the unique solution of the dynamic equation $Y^\Delta(t) = A(t)Y(t)$ such that $Y(t_0) = I$.

5. Almost automorphic solutions of first order linear dynamic equations on time scales

In this section, our goal is to prove existence of an almost automorphic solution of first order linear dynamic equation on time scales given by

(5.1) $x^\Delta(t) = A(t)x(t) + f(t)$

where $A : \mathbb{T} \to \mathbb{R}^{n \times n}$, $f : \mathbb{T} \to \mathbb{R}^n$ and its associated homogeneous equation

(5.2) $x^\Delta(t) = A(t)x(t)$.

Throughout this section, we assume that $A(t)$ is almost automorphic on $\mathbb{T}$, which means that given a sequence $(\alpha'_n) \in \Pi$, there exists a subsequence $(\alpha_n) \subset (\alpha'_n)$ such that

(5.3) $\lim_{n \to \infty} A(t + \alpha_n) = \bar{A}(t)$

exists and is well-defined for every $t \in \mathbb{T}$ and

(5.4) $\lim_{n \to \infty} \bar{A}(t - \alpha_n) = A(t)$

for every $t \in \mathbb{T}$.

Also, consider the following linear dynamic system

(5.5) $x^\Delta(t) = \bar{A}(t)x(t)$.

Before to proceed, we present a result which will be fundamental to our objectives. It can be found in [44], Lemma 2.9 for the case $\mathbb{T} = \mathbb{Z}$. We give the proof here for the general case.

Lemma 5.1. Let $\mathbb{T}$ be invariant under translations and $A(t)$ be almost automorphic and a non-singular matrix on $\mathbb{T}$. Also, suppose that the set $\{A^{-1}(t)\}_{t \in \mathbb{T}}$ is bounded. Then $A^{-1}(t)$ is almost automorphic on $\mathbb{T}$, that is, for every sequence $(\alpha'_n) \in \Pi$, there exists a subsequence $(\alpha_n) \subset (\alpha'_n)$ such that

(5.6) $\lim_{n \to \infty} A^{-1}(t + \alpha_n) =: \bar{A}^{-1}(t)$

is well defined for each $t \in \mathbb{T}$ and

(5.7) $\lim_{n \to \infty} \bar{A}^{-1}(t - \alpha_n) = A^{-1}(t)$

for each $t \in \mathbb{T}$. 
Proof. Let \((\alpha'_n)\) be a sequence on \(\Pi\). Since \(A(t)\) is almost automorphic on time scales, there exists a subsequence \((\alpha_n)\) such that

\[
\lim_{n \to \infty} A(t + \alpha_n) =: \bar{A}(t)
\]

is well defined for each \(t \in \mathbb{T}\) and

\[
\lim_{n \to \infty} \bar{A}(t - \alpha_n) = A(t)
\]

for each \(t \in \mathbb{T}\).

Fix \(t \in \mathbb{T}\) and define \(A_n := A(t + \alpha_n), n \in \mathbb{N}\). By hypothesis, the set \(\{A_n^{-1}\}_{n \in \mathbb{N}}\) is bounded. Using the identity

\[
A_n^{-1} - A_m^{-1} = A_n^{-1}(A_m - A_n)A_m^{-1}
\]

and the fact that \(\{A_n\}\) is a Cauchy sequence, it follows that \(\{A_n^{-1}\}\) is a Cauchy sequence. Hence, there exists a matrix \(T\) (for each \(t \in \mathbb{T}\) fixed) such that

\[
A_n^{-1} \to T(t).
\]

Taking the limit of \(A_nA_n^{-1} = A_n^{-1}A_n = I\), where \(I\) denotes the identity matrix, we obtain that \(A(t)\) is invertible and \(\bar{A}^{-1}(t) = T(t)\) for each \(t \in \mathbb{T}\). Since the map \(A \to A^{-1}\) is continuous on the set of non-singular matrices, it follows that

\[
\lim_{n \to \infty} A^{-1}(t + \alpha_n) = \bar{A}^{-1}(t)
\]

for each \(t \in \mathbb{T}\). Analogously, one can prove that

\[
\lim_{n \to \infty} \bar{A}^{-1}(t - \alpha_n) = A^{-1}(t),
\]

for each \(t \in \mathbb{T}\).

As an immediate consequence, we obtain for the following result for a particular case.

**Corollary 5.2.** Let \(\mathbb{T}\) be invariant under translations and \(A(t)\) be almost automorphic and a regressive matrix on \(\mathbb{T}\). Also, suppose that the set \(\{(I + A(t)\mu(t))^{-1}\}_{t \in \mathbb{T}}\) is bounded. Then \((I + A(t)\mu(t))^{-1}\) is almost automorphic on \(\mathbb{T}\), that is, for every sequence \((\alpha'_n) \in \Pi\), there exists a subsequence \((\alpha_n) \subset (\alpha'_n)\) such that

\[
\lim_{n \to \infty} (I + A(t + \alpha_n)\mu(t + \alpha_n))^{-1} =: (I + \bar{A}(t)\bar{\mu}(t))^{-1}
\]

is well defined for each \(t \in \mathbb{T}\) and

\[
\lim_{n \to \infty} (I + \bar{A}(t - \alpha_n)\bar{\mu}(t - \alpha_n))^{-1} = (I + A(t)\mu(t))^{-1}
\]

for each \(t \in \mathbb{T}\).

**Proof.** Denote \(B(t) := (I + A(t)\mu(t))\), for every \(t \in \mathbb{T}\). Since \(A(t)\) and \(\mu(t)\) are almost automorphic functions, for every sequence \((\alpha'_n)\) on \(\Pi\), there exists a subsequence \((\alpha_n) \subset (\alpha'_n)\) such that

\[
\lim_{n \to \infty} A(t + \alpha_n) = \bar{A}(t) \quad \text{and} \quad \lim_{n \to \infty} \mu(t - \alpha_n) = \bar{\mu}(t)
\]

is well-defined and exists for every \(t \in \mathbb{T}\) and

\[
\lim_{n \to \infty} \bar{A}(t - \alpha_n) = A(t) \quad \text{and} \quad \lim_{n \to \infty} \bar{\mu}(t - \alpha_n) = \mu(t)
\]
for every $t \in \mathbb{T}$. Thus, it follows that
\[
\lim_{n \to \infty} B(t + \alpha_n) = \lim_{n \to \infty} (I + A(t + \alpha_n)\mu(t + \alpha_n)) = I + \bar{A}(t)\bar{\mu}(t) := \bar{B}(t)
\]
for every $t \in \mathbb{T}$ and
\[
\lim_{n \to \infty} \bar{B}(t - \alpha_n) = \lim_{n \to \infty} (I + \bar{A}(t - \alpha_n)\bar{\mu}(t - \alpha_n)) = I + A(t)\mu(t) = B(t).
\]

Therefore, $B(t)$ is almost automorphic on $\mathbb{T}$. Also, since $A(t)$ is a regressive matrix, it follows that $B(t)$ is non-singular on $\mathbb{T}$. By hypothesis, $\{B^{-1}(t)\}_{t \in \mathbb{T}}$ is bounded. Thus, all the hypotheses of Lemma 5.1 are satisfied. As a consequence, we obtain that $B^{-1}(t) = (I + A(t)\mu(t))^{-1}$ is almost automorphic on $\mathbb{T}$, that is, for every sequence $(\alpha'_n)$ on $\Pi$, there exists a subsequence $(\alpha_n) \subset (\alpha'_n)$ such that
\[
\lim_{n \to \infty} B^{-1}(t + \alpha_n) =: \bar{B}^{-1}(t)
\]
is well defined and exists for each $t \in \mathbb{T}$ and
\[
\lim_{n \to \infty} \bar{B}^{-1}(t - \alpha_n) = B^{-1}(t)
\]
for each $t \in \mathbb{T}$. It implies that
\[
\lim_{n \to \infty} (I + A(t + \alpha_n)\mu(t + \alpha_n))^{-1} =: (I + \bar{A}(t)\bar{\mu}(t))^{-1}
\]
is well defined for each $t \in \mathbb{T}$ and
\[
\lim_{n \to \infty} (I + \bar{A}(t - \alpha_n)\bar{\mu}(t - \alpha_n))^{-1} = (I + A(t)\mu(t))^{-1}
\]
for each $t \in \mathbb{T}$ and the result follows as well. \qed

Now, we present some auxiliaries results lemma which will be essential to our purposes.

**Lemma 5.3.** Let $\mathbb{T}$ be an invariant under translations and $A \in \mathcal{R}(\mathbb{T}, \mathbb{R}^{n \times n})$ is almost automorphic and nonsingular on $\mathbb{T}$ and $\{A^{-1}(t)\}_{t \in \mathbb{T}}$ and $\{(I + \mu(t)A(t))^{-1}\}_{t \in \mathbb{T}}$ are bounded on $\mathbb{T}$, then for every sequence $(\alpha'_n) \in \Pi$, there exists a subsequence $(\alpha_n) \subset (\alpha'_n)$ such that
\[
\lim_{n \to \infty} X(t + \alpha_n)X^{-1}(s + \alpha_n) = W(t, s)
\]
for every $s, t \in \mathbb{T}$, $s < t$ and
\[
\lim_{n \to \infty} W(t - \alpha_n, s - \alpha_n) = X(t)X^{-1}(s),
\]
for every $s, t \in \mathbb{T}$ and $s < t$, where $X(t)$ is the fundamental matrices of (5.2) and $W(t, s) := \prod_{s}^{t}(I + \bar{A}(\tau)\Delta \tau)$

**Proof.** Since $X(t)$ is the fundamental matrix of (5.2), we obtain by Theorem 4.8
\[
X(t) = \prod_{t_0}^{t}(I + A(\tau)\Delta \tau)
\]
which implies the following

\[
X^{-1}(t) = (X(t))^{-1} = \left( \prod_{t_0}^{t} (I + A(\tau)\Delta\tau) \right)^{-1}.
\]

Notice that, by Theorem 4.7, \( \Pi'_0 (I + A(\tau)\Delta\tau) \) is a nonsingular matrix, since \( A \in \mathcal{R}(\mathbb{T}, \mathbb{R}^{n \times n}) \). By the almost automorphicity of \( A(t) \), we obtain that for every sequence \( (\alpha'_n) \in \Pi \), there exists a subsequence \( (\alpha_n) \subset (\alpha'_n) \) such that

\[
X(t + \alpha_n)X^{-1}(s + \alpha_n) = \prod_{t_0}^{t+\alpha_n} (I + A(\tau)\Delta\tau) \left( \prod_{t_0}^{s+\alpha_n} (I + A(\tau)\Delta\tau) \right)^{-1} = \prod_{t_0}^{t} (I + A(\tau)\Delta\tau) \prod_{s+\alpha_n}^{t} (I + A(\tau + \alpha_n)\Delta\tau),
\]

by Theorem 4.5. Applying the limit in both sides, we obtain

\[
\lim_{n \to \infty} X(t + \alpha_n)X^{-1}(s + \alpha_n) = \lim_{n \to \infty} \prod_{t_0}^{t} (I + A(\tau + \alpha_n)\Delta\tau) = \prod_{t_0}^{t} (I + \bar{A}(\tau)\Delta\tau) := W(t, s),
\]

since the product \( \Delta \)-integral is a continuous function, by Theorem 4.6.

We also point out that \( \bar{A} \) is Riemann \( \Delta \)-integrable, since \( \bar{A} \) is a bounded function (see [12]). And thus, by Theorem 4.3, \( \bar{A} \) is also product \( \Delta \)-integrable.

Analogously, one can prove that

\[
\lim_{n \to \infty} W(t - \alpha_n, s - \alpha_n) = X(t)X^{-1}(s).
\]

\[\square\]

**Remark 5.4.** It is clear that from the previous result, by the same hypothesis, we obtain as a consequence the following

\[
\lim_{n \to \infty} X(t + \alpha_n)PX^{-1}(s + \alpha_n) = PW(t, s)
\]

and

\[
\lim_{n \to \infty} PW(t - \alpha_n, s - \alpha_n) = X(t)PX^{-1}(s),
\]

for a projection \( P \) described in Definition 2.12 and also, we have

\[
\lim_{n \to \infty} X(t + \alpha_n)(I - P)X^{-1}(s + \alpha_n) = (I - P)W(t, s)
\]

and

\[
\lim_{n \to \infty} (I - P)W(t - \alpha_n, s - \alpha_n) = X(t)(I - P)X^{-1}(s).
\]

**Lemma 5.5.** Let \( \mathbb{T} \) be an invariant under translations time scale, \( A(t) \in \mathcal{R}(\mathbb{T}, \mathbb{R}^{n \times n}) \) be almost automorphic and nonsingular on \( \mathbb{T} \) and the sets \( \{A^{-1}(t)\}_{t \in \mathbb{T}} \) and \( \{(I + \mu(t)A(t))^{-1}\}_{t \in \mathbb{T}} \) are bounded on \( \mathbb{T} \). Also, suppose the system (5.2) has an exponential dichotomy with positive
constants \( K \) and \( \gamma \). Then, given a sequence \((\alpha'_n) \in \Pi\), there exists a subsequence \((\alpha_n) \subset (\alpha'_n)\) such that

\[
(5.10) \quad \lim_{n \to \infty} X(t + \alpha_n)PX^{-1}(\sigma(s + \alpha_n)) = PW(t, s) \left( I + \bar{A}(s)\bar{\mu}(s) \right)^{-1} := Y(t, s)
\]

exists and is well defined for \( t \in \mathbb{T} \) and

\[
(5.11) \quad \lim_{n \to \infty} Y(t - \alpha_n, s - \alpha_n) = X(t)PX^{-1}(\sigma(s)),
\]

where \( \bar{\mu}(t) \) is given by (3.2) and (3.3), \( X(t) \) is the fundamental matrix of (5.2) and \( W(t, s) = \prod_{\tau=s}^{t} (I + A(\tau)) \). Similarly, we have that given a sequence \((\alpha'_n) \in \Pi\), there exists a subsequence \((\alpha_n) \subset (\alpha'_n)\) such that

\[
(5.12) \quad \lim_{n \to \infty} X(t + \alpha_n)(I - P)X^{-1}(\sigma(s + \alpha_n)) = (I - P)W(t, s) \left( I + \bar{A}(s)\bar{\mu}(s) \right)^{-1} := Z(t, s)
\]

exists and is well defined for \( t \in \mathbb{T} \) and

\[
(5.13) \quad \lim_{n \to \infty} Z(t - \alpha_n, s - \alpha_n) = X(t)(I - P)X^{-1}(\sigma(s)),
\]

Proof. Since \( X(t) \) is the fundamental matrix of (5.2), we have for \( s < t \)

\[
X(t + \alpha_n)PX^{-1}(\sigma(s + \alpha_n)) = X(t + \alpha_n)PX^{-1}(s + \alpha_n)X(s + \alpha_n)X^{-1}(\sigma(s + \alpha_n))
\]

\[
= X(t + \alpha_n)PX^{-1}(s + \alpha_n) \left( \prod_{\sigma(s + \alpha_n)}^{s + \alpha_n} (I + A(\tau)\Delta\tau) \right)^{-1}
\]

\[
= X(t + \alpha_n)PX^{-1}(s + \alpha_n) \left( \prod_{s + \alpha_n}^{\sigma(s + \alpha_n)} (I + A(\tau)\Delta\tau) \right)^{-1}
\]

\[
= X(t + \alpha_n)PX^{-1}(s + \alpha_n) (I + A(s + \alpha_n)\mu(s + \alpha_n))^{-1}.
\]

Applying the limit as \( n \to \infty \), we have

\[
\lim_{n \to \infty} X(t + \alpha_n)PX^{-1}(\sigma(s + \alpha_n)) = PW(t, s) \left( I + \bar{A}(s)\bar{\mu}(s) \right)^{-1} := Y(t, s),
\]

by Remark 5.4, the automorphicity of \( \mu \) and using the fact that the map \( I + A(s)\mu(s) \mapsto (I + A(s)\mu(s))^{-1} \) is continuous on the set of regressive matrices. Notice that \( (I + \bar{A}(s)\bar{\mu}(s))^{-1} \) is well-defined, by Corollary 5.2. We remind that the projection \( P \) commutes with \( X(t) \) (see Definition 2.12).
Reciprocally, we have
\[
\lim_{n \to \infty} Y(t - \alpha_n, s - \alpha_n) := \lim_{n \to \infty} P W(t - \alpha_n, s - \alpha_n) \left( I + \bar{A}(s - \alpha_n) \bar{\mu}(s - \alpha_n) \right)^{-1} \\
= X(t) P X^{-1}(s) \left( I + A(s) \mu(s) \right)^{-1} \\
= X(t) P X^{-1}(s) \left( \prod_{\sigma(s)} (I + A(\tau) \Delta \tau) \right)^{-1} \\
= X(t) P X^{-1}(s) \prod_{\sigma(s)} (I + A(\tau) \Delta \tau) \\
= X(t) P X^{-1}(s) X(s) X^{-1}(\sigma(s)) = X(t) P X^{-1}(\sigma(s)),
\]
Similarly, we obtain
\[
X(t + \alpha_n)(I - P) X^{-1}(\sigma(s + \alpha_n)) = X(t + \alpha_n)(I - P) X^{-1}(s + \alpha_n) X(s + \alpha_n) X^{-1}(\sigma(s + \alpha_n)) \\
= X(t + \alpha_n)(I - P) X^{-1}(s + \alpha_n) \left( \prod_{\sigma(s + \alpha_n)} (I + A(\tau) \Delta \tau) \right)^{-1} \\
= X(t + \alpha_n)(I - P) X^{-1}(s + \alpha_n) \prod_{s + \alpha_n} (I + A(\tau) \Delta \tau) \\
= X(t + \alpha_n)(I - P) X^{-1}(s + \alpha_n) (I + A(s + \alpha_n) \mu(s + \alpha_n))^{-1}.
\]
Applying the limit as \( n \to \infty \), we have
\[
\lim_{n \to \infty} X(t + \alpha_n)(I - P) X^{-1}(\sigma(s + \alpha_n)) = (I - P) W(t, s) \left( I + \bar{A}(s) \bar{\mu}(s) \right)^{-1} := Z(t, s),
\]
by Remark 5.4, the automorphicity of \( \mu \) and using the fact that the map \( I + A(s) \mu(s) \mapsto (I + A(s) \mu(s))^{-1} \) is continuous on the set of regressive matrices.

Reciprocally, we have
\[
\lim_{n \to \infty} Z(t - \alpha_n, s - \alpha_n) := \lim_{n \to \infty} (I - P) W(t - \alpha_n, s - \alpha_n) \left( I + \bar{A}(s - \alpha_n) \bar{\mu}(s - \alpha_n) \right)^{-1} \\
= X(t)(I - P) X^{-1}(s) \left( I + A(s) \mu(s) \right)^{-1} \\
= X(t)(I - P) X^{-1}(s) \left( \prod_{\sigma(s)} (I + A(\tau) \Delta \tau) \right)^{-1} \\
= X(t)(I - P) X^{-1}(s) \prod_{\sigma(s)} (I + A(\tau) \Delta \tau) \\
= X(t)(I - P) X^{-1}(s) X(s) X^{-1}(\sigma(s)) = X(t)(I - P) X^{-1}(\sigma(s)),
\]
and the result follows as well. \( \square \)

Now, we present our main result in this section. The next result ensures that the system (5.1) has an almost automorphic solution.
Theorem 5.6. Let $\mathbb{T}$ be an invariant under translations time scale and $A \in \mathcal{R}(\mathbb{T}, \mathbb{R}^{n \times n})$ be almost automorphic and nonsingular on $\mathbb{T}$ and $\{A^{-1}(t)\}_{t \in \mathbb{T}}$ and $\{(I + \mu(t)A(t))^{-1}\}_{t \in \mathbb{T}}$ are bounded. Also, suppose the equation (5.2) admits an exponential dichotomy with positive constants $K$ and $\gamma$ and $f \in \mathcal{C}_{ad}(\mathbb{T}, \mathbb{R}^n)$ is almost automorphic function on time scales. Then the equation (5.1) has an almost automorphic solution.

Proof. By Theorem 2.15, we have that the following function

\begin{equation}
(5.14) \quad x(t) = \int_{-\infty}^{t} X(t)PX^{-1}(\sigma(s))f(s)\Delta s - \int_{t}^{+\infty} X(t)(I - P)X^{-1}(\sigma(s))f(s)\Delta s
\end{equation}

is a bounded solution of (2.1). It remains to prove that $x : \mathbb{T} \to \mathbb{R}^n$ is an almost automorphic function.

By the automorphicity of functions $A(t)$, $f(t)$ and $\mu(t)$, it follows that for every sequence $(\alpha'_n)$ on $\Pi$, there exists a subsequence $(\alpha_n) \subset (\alpha'_n)$ such that

\[ \lim_{n \to \infty} A(t + \alpha_n) = \bar{A}(t), \quad \lim_{n \to \infty} f(t + \alpha_n) = \bar{f}(t) \quad \text{and} \quad \lim_{n \to \infty} \mu(t + \alpha_n) = \bar{\mu}(t) \]

is well-defined and exists for every $t \in \mathbb{T}$ and

\[ \lim_{n \to \infty} \bar{A}(t - \alpha_n) = A(t), \quad \lim_{n \to \infty} \bar{f}(t - \alpha_n) = f(t) \quad \text{and} \quad \lim_{n \to \infty} \bar{\mu}(t - \alpha_n) = \mu(t) \]

for every $t \in \mathbb{T}$.

Let us denote

\[ M(t) = \int_{-\infty}^{t} X(t)PX^{-1}(\sigma(s))f(s)\Delta s \]

and

\[ \bar{M}(t) = \int_{-\infty}^{t} Y(t, s)\bar{f}(s)\Delta s, \]

where $Y(t, s)$ is given by (5.10).

Then, we have

\[ \| M(t + \alpha_n) - \bar{M}(t) \|
\]

\[ = \left\| \int_{-\infty}^{t + \alpha_n} X(t + \alpha_n)PX^{-1}(\sigma(s))f(s)\Delta s - \int_{-\infty}^{t} Y(t, s)\bar{f}(s)\Delta s \right\|
\]

\[ = \left\| \int_{-\infty}^{t} X(t + \alpha_n)PX^{-1}(\sigma(s + \alpha_n))f(s + \alpha_n)\Delta s - \int_{-\infty}^{t} Y(t, s)\bar{f}(s)\Delta s \right\|
\]

\[ \leq \left\| \int_{-\infty}^{t} X(t + \alpha_n)PX^{-1}(\sigma(s + \alpha_n))f(s + \alpha_n)\Delta s - \int_{-\infty}^{t} X(t + \alpha_n)PX^{-1}(\sigma(s + \alpha_n))\bar{f}(s)\Delta s \right\|
\]

\[ + \left\| \int_{-\infty}^{t} X(t + \alpha_n)PX^{-1}(\sigma(s + \alpha_n))\bar{f}(s)\Delta s - \int_{-\infty}^{t} Y(t, s)\bar{f}(s)\Delta s \right\|
\]

\[ = \left\| \int_{-\infty}^{t} X(t + \alpha_n)PX^{-1}(\sigma(s + \alpha_n))[f(s + \alpha_n) - \bar{f}(s)]\Delta s \right\|
\]

\[ + \left\| \int_{-\infty}^{t} [X(t + \alpha_n)PX^{-1}(\sigma(s + \alpha_n)) - Y(t, s)]\bar{f}(s)\Delta s \right\|. \]
Applying limit as $n \to \infty$ and using the fact that $\bar{f}$ is a bounded function (this fact follows by automorphy of $f$) and the exponential dichotomy of equation (5.2), we obtain

$$\lim_{n \to \infty} M(t + \alpha_n) = \bar{M}(t)$$

for each $t \in \mathbb{T}$. Similarly, we can prove

$$\lim_{n \to \infty} \bar{M}(t - \alpha_n) = M(t)$$

for each $t \in \mathbb{T}$.

Let us denote

$$N(t) = \int_t^{+\infty} X(t)(I - P)X^{-1}(s)f(s)\Delta s$$

and

$$\bar{N}(t) = \int_t^{+\infty} Z(t, s)\bar{f}(s)\Delta s,$$

where $Z(t, s)$ is given by (5.12).

Then, the same way as before, one can prove that given a sequence $(\alpha'_n) \in \Pi$, there exists a subsequence $(\alpha_n) \subset (\alpha'_n)$ such that

$$\lim_{n \to \infty} N(t + \alpha_n) = \bar{N}(t)$$

for every $t \in \mathbb{T}$ and

$$\lim_{n \to \infty} \bar{N}(t - \alpha_n) = N(t)$$

for each $t \in \mathbb{T}$.

Now, define $\bar{x}(t) = \bar{M}(t) + \bar{N}(t)$, then using the definition of $x$ from (5.14), we obtain as an immediate consequence that

$$\lim_{n \to \infty} x(t + \alpha_n) = \bar{x}(t)$$

is well-defined for every $t \in \mathbb{T}$ and

$$\lim_{n \to \infty} \bar{x}(t - \alpha_n) = x(t)$$

for each $t \in \mathbb{T}$.

Thus, $x$ is an almost automorphic function and we get the desired result. \hfill \Box

**Remark 5.7.** It is clear that the previous theorem remains valid for linear nabla dynamic equations on time scales. In the other words, one can prove analogously that the nabla dynamic equation

$$x^\nabla(t) = A(t)x(t) + f(t),$$

where $A : \mathbb{T} \to \mathbb{R}^{n \times n}$ and $f : \mathbb{T} \to \mathbb{R}^{n}$, has an almost automorphic solution, under similar conditions to the ones presented in Theorem 5.6.

Choosing $\mathbb{T} = \mathbb{Z}$ in the Theorem 5.6, we obtain a result for difference equations. It is the content of the next result.
Corollary 5.8. Let $A : \mathbb{Z} \to \mathbb{R}^{n \times n}$ be almost automorphic, regulated and nonsingular matrix function. Also, suppose that $\{A^{-1}(k)\}_{k \in \mathbb{Z}}$ is bounded. Moreover, assume that $(I + A(t))$ is nonsingular matrix function and $\{(I + A(k))^{-1}\}_{k \in \mathbb{Z}}$ is bounded, the equation
\[ x(k + 1) = A(k)x(k) \]
admits an exponential dichotomy with positive constants $K$ and $\gamma$ and the function $f : \mathbb{Z} \to \mathbb{R}^n$ is almost automorphic and regulated. Then the equation
\[ x(k + 1) = A(k)x(k) + f(k) \]
has an almost automorphic solution.

Similarly, we can take $T = h\mathbb{Z}$ in Theorem 5.6 and obtain an interesting result for a different type of difference equations.

Corollary 5.9. Let $A : h\mathbb{Z} \to \mathbb{R}^{n \times n}$ be almost automorphic, regulated and nonsingular matrix function. Also, suppose that $\{A^{-1}(k)\}_{k \in h\mathbb{Z}}$ is bounded. Moreover, assume that $(I + hA(t))$ is nonsingular matrix function and $\{(I + hA(k))^{-1}\}_{k \in h\mathbb{Z}}$ is bounded, the equation
\[ x(k + h) = A(k)x(k) \]
admits an exponential dichotomy with positive constants $K$ and $\gamma$ and the function $f : h\mathbb{Z} \to \mathbb{R}^n$ is almost automorphic and regulated. Then the equation
\[ x(k + h) = A(k)x(k) + f(k) \]
has an almost automorphic solution.

Now, taking $T = \mathbb{R}$ in Theorem 5.6, one can obtain a result for ordinary differential equations.

Corollary 5.10. Let $A : \mathbb{R} \to \mathbb{R}^{n \times n}$ be almost automorphic, continuous and non-singular matrix function and $\{A^{-1}(t)\}_{t \in \mathbb{R}}$ is bounded. Assume also the equation
\[ \dot{x}(t) = A(t)x(t) \]
admits an exponential dichotomy with positive constants $K$ and $\gamma$ and the function $f : \mathbb{R} \to \mathbb{R}^n$ is almost automorphic and continuous. Then the equation
\[ \dot{x}(t) = A(t)x(t) + f(t) \]
has an almost automorphic solution.

Finally, we choose $T = P_{a,\cos a}$ and obtain an interesting result. We do not know any result concerning almost automorphic treating about this case.

Corollary 5.11. Let $A : P_{a,\cos a} \to \mathbb{R}^{n \times n}$, for $0 < a < \frac{\pi}{2}$ be almost automorphic and, for every $k \in \mathbb{Z}$, be continuous at $[k(a + \cos a), k(a + \cos a) + a]$, regulated at $k(a + \cos a) + a$ and a nonsingular matrix function. Also, suppose that $\{A^{-1}(t)\}_{t \in P_{a,\cos a}}$ is bounded. Moreover, assume that $(I + (\cos t)A(t))$ is nonsingular matrix function and $\{(I + (\cos t)A(t))^{-1}\}_{t \in P_{a,\cos a}}$ is bounded and the equation
\[ x^\Delta(t) = A(t)x(t) \]
admits an exponential dichotomy with positive constants $K$ and $\gamma$ and the function $f : \mathbb{P}_{a, \cos a} \to \mathbb{R}^n$ is almost automorphic and, for every $k \in \mathbb{N}$, be continuous at $[k(a+\cos a), k(a+\cos a) + a]$ and regulated at $k(a + \cos a) + a$. Then the equation

$$x^\Delta(t) = A(t)x(t) + f(t)$$

has an almost automorphic solution.

6. **Almost Automorphic Solutions for Semilinear Dynamic Equations on Time Scales**

In this section, consider the following semilinear dynamic equation

$$x^\Delta(t) = A(t)x(t) + f(t,x) \quad (6.1)$$

where $A : \mathbb{T} \to \mathbb{R}^{n \times n}$ and $f : \mathbb{T} \times \mathbb{R}^n \to \mathbb{R}^n$ and its associated homogeneous equation

$$x^\Delta(t) = A(t)x(t). \quad (6.2)$$

Also, consider the following linear dynamic system

$$x^\Delta(t) = \bar{A}(t)x(t), \quad (6.3)$$

where $\bar{A}(t)$ is given by (5.3) and (5.4).

Now, we introduce a definition of solution of (6.1) in a strict sense. Here, we will restrict ourselves for this concept of solution for (6.1).

**Definition 6.1.** We say that $x : \mathbb{T} \to \mathbb{R}^n$ is a solution of (6.1) if $x$ satisfies the following equation

$$x(t) = \int_{-\infty}^{t} X(t)P^{-1}(\sigma(s))f(s,x(s))\Delta s - \int_{t}^{+\infty} X(t)(I-P)P^{-1}(\sigma(s))f(s,x(s))\Delta s. \quad (6.4)$$

**Remark 6.2.** We point out that the previous definition makes sense. In fact, suppose $x(t)$ satisfies the equation (6.4), then

$$x^\Delta(t) - A(t)x(t) =$$

$$= X^\Delta(t) \int_{-\infty}^{t} P^{-1}(\sigma(s))f(s,x(s))\Delta s + X(\sigma(t))P^{-1}(\sigma(t))f(t,x(t))$$

$$- X^\Delta \int_{t}^{+\infty} (I-P)P^{-1}(\sigma(s))f(s,x(s))\Delta s + X(\sigma(t))(I-P)P^{-1}(\sigma(t))f(t,x(t))$$

$$- A(t)X(t) \int_{-\infty}^{t} P^{-1}(\sigma(s))f(s,x(s))\Delta s + A(t)X(t) \int_{t}^{+\infty} (I-P)P^{-1}(\sigma(s))f(s,x(s))\Delta s$$

which implies

$$x^\Delta = A(t)x(t) + f(t,x(t)).$$

The proof of Remark 6.2 follows analogously the proof of Lemma 2.13 from [40]. We reproduce it here for reader’s convenience.

In the sequel, we present an existence and uniqueness result of an almost automorphic solution of (6.1).
Theorem 6.3. Let $\mathbb{T}$ be an invariant under translations time scale and $f \in C_{rd}(\mathbb{T} \times \mathbb{R}^n, \mathbb{R}^n)$ be almost automorphic with respect to the first variable. Assume that $A \in \mathcal{R}(\mathbb{T}, \mathbb{R}^{n \times n})$ is almost automorphic and nonsingular matrix function, the sets $\{A^{-1}(t)\}_{t \in \mathbb{T}}$ and $\{(I + \mu(t)A(t))^{-1}\}_{t \in \mathbb{T}}$ are bounded. Suppose also the equation (6.2) admits an exponential dichotomy on $\mathbb{T}$ with positive constants $K$ and $\gamma$ and the following conditions are fulfilled:

(i) There exists a constant $0 < L < \frac{\gamma}{2K(2 + \bar{\mu}\gamma)}$ such that

$$
\|f(t, x) - f(t, y)\| \leq L\|x - y\|,
$$

for every $x, y \in \mathbb{R}^n$ and $t \in \mathbb{T}$, where $\bar{\mu} = \sup_{t \in \mathbb{T}} |\mu(t)|$.

Then, the system (6.1) has a unique solution which is almost automorphic.

Proof. Define an operator $T : AA_T(\mathbb{R}^n) \rightarrow AA_T(\mathbb{R}^n)$ as follows:

$$(Tu)(t) = \int_{-\infty}^{t} X(t)PX^{-1}(\sigma(s))f(s, u(s))\Delta s - \int_{t}^{+\infty} X(t)(I - P)X^{-1}(\sigma(s))f(s, u(s))\Delta s,$$

for all $u \in AA_T(\mathbb{R}^n)$.

Now, let us prove that $Tu \in AA_T(\mathbb{R}^n)$. Since $f$ satisfies the Lipschitz condition, we obtain by Theorem 3.23 that $f(\cdot, u(\cdot))$ is almost automorphic, using the fact that $f, u \in AA_T(\mathbb{R}^n)$. Since $u \in AA_T(\mathbb{R}^n)$, then for every sequence $(\alpha_n^\prime) \in \Pi$, there exists a subsequence $(\alpha_n^\prime_n) \subset (\alpha_n^\prime)$ such that

$$
\lim_{n \to \infty} u(t + \alpha_n^\prime) = \bar{u}(t)
$$

is well-defined for every $t \in \mathbb{T}$ and

$$
\lim_{n \to \infty} \bar{u}(t - \alpha_n) = u(t),
$$

for each $t \in \mathbb{T}$.

Moreover, by the automorphicity of $f$, we obtain there exists a subsequence $(\alpha_n) \subset (\alpha_n^\prime_n)$ such that

$$
\lim_{n \to \infty} f(t + \alpha_n^\prime, u) = \bar{f}(t, u)
$$

is well-defined for every $t \in \mathbb{T}, u \in \mathbb{R}^n$ and

$$
\lim_{n \to \infty} \bar{f}(t - \alpha_n, u) = f(t, u),
$$

for each $t \in \mathbb{T}$.

By Lemma 5.5, we obtain

$$
\lim_{n \to \infty} X(t + \alpha_n)PX^{-1}(\sigma(s + \alpha_n)) = Y(t, s)
$$

exists and is well defined for $t \in \mathbb{T}$ and

$$
\lim_{n \to \infty} Y(t - \alpha_n, s - \alpha_n) = X(t)PX^{-1}(\sigma(s)),
$$

where $X(t)$ is the fundamental matrix of (6.2) and $Y(t, s)$ is given by (5.10).

Similarly, by Lemma 5.5, we get

$$
\lim_{n \to \infty} X(t + \alpha_n)(I - P)X^{-1}(\sigma(s + \alpha_n)) = Z(t, s)
$$
exists and is well defined for \( t \in \mathbb{T} \) and
\[
\lim_{n \to \infty} Z(t - \alpha_n, s - \alpha_n) = X(t)(I - P)X^{-1}(\sigma(s)),
\]
where \( X(t) \) is the fundamental matrix of (6.2) and \( Z(t, s) \) is given by (5.12).

Let us define the following function:
\[
h(t) = \int_{-\infty}^{t} Y(t, s) \bar{f}(s, \bar{u}(s)) \Delta s - \int_{t}^{+\infty} Z(t, s) \bar{f}(s, \bar{u}(s)) \Delta s,
\]
for every \( t \in \mathbb{T} \).

Then, we obtain
\[
\|(Tu)(t+\alpha_n)-h(t)\| \leq \left\| \int_{-\infty}^{t} X(t + \alpha_n)PX^{-1}(\sigma(s))f(s, u(s)) \Delta s - \int_{t}^{t+\alpha_n} Y(t, s) \bar{f}(s, \bar{u}(s)) \Delta s \right\|
\]
\[
+ \left\| \int_{t+\alpha_n}^{+\infty} X(t + \alpha_n)(I - P)X^{-1}(\sigma(s))f(s, u(s)) \Delta s - \int_{t}^{+\infty} Z(t, s) \bar{f}(s, \bar{u}(s)) \Delta s \right\|
\]
\[
= \left\| \int_{-\infty}^{t} X(t + \alpha_n)PX^{-1}(\sigma(s + \alpha_n))f(s + \alpha_n, u(s + \alpha_n)) \Delta s - \int_{t}^{t} Y(t, s) \bar{f}(s, \bar{u}(s)) \Delta s \right\|
\]
\[
+ \left\| \int_{t}^{+\infty} X(t + \alpha_n)(I - P)X^{-1}(\sigma(s + \alpha_n))f(s + \alpha_n, u(s + \alpha_n)) \Delta s - \int_{t}^{+\infty} Z(t, s) \bar{f}(s, \bar{u}(s)) \Delta s \right\|
\]
\[
\leq \int_{-\infty}^{t} \| X(t + \alpha_n)PX^{-1}(\sigma(s + \alpha_n)) - Y(t, s) \| \| \bar{f}(s, \bar{u}(s)) \| \Delta s
\]
\[
+ \int_{-\infty}^{t} \| X(t + \alpha_n)PX^{-1}(\sigma(s + \alpha_n)) \| \| f(s + \alpha_n, u(s + \alpha_n)) - \bar{f}(s, \bar{u}(s)) \| \Delta s
\]
\[
+ \int_{t}^{+\infty} \| X(t + \alpha_n)(I - P)X^{-1}(\sigma(s + \alpha_n)) - Z(t, s) \| \| \bar{f}(s, \bar{u}(s)) \| \Delta s
\]
\[
+ \int_{t}^{+\infty} \| X(t + \alpha_n)(I - P)X^{-1}(\sigma(s + \alpha_n)) \| \| f(s + \alpha_n, u(s + \alpha_n) - \bar{f}(s, \bar{u}(s)) \| \Delta s.
\]

Applying the limit as \( n \to \infty \) in both sides, we obtain
\[
\lim_{n \to \infty} \|(Tu)(t+\alpha_n)-h(t)\| \leq \lim_{n \to \infty} \int_{-\infty}^{t} \| X(t + \alpha_n)PX^{-1}(\sigma(s + \alpha_n)) - Y(t, s) \| \| \bar{f}(s, \bar{u}(s)) \| \Delta s
\]
\[
+ \lim_{n \to \infty} \int_{-\infty}^{t} \| X(t + \alpha_n)PX^{-1}(\sigma(s + \alpha_n)) \| \| f(s + \alpha_n, u(s + \alpha_n)) - \bar{f}(s, \bar{u}(s)) \| \Delta s
\]
\[
+ \lim_{n \to \infty} \int_{t}^{+\infty} \| X(t + \alpha_n)(I - P)X^{-1}(\sigma(s + \alpha_n)) - Z(t, s) \| \| \bar{f}(s, \bar{u}(s)) \| \Delta s
\]
\[
+ \lim_{n \to \infty} \int_{t}^{+\infty} \| X(t + \alpha_n)(I - P)X^{-1}(\sigma(s + \alpha_n)) \| \| f(s + \alpha_n, u(s + \alpha_n) - \bar{f}(s, \bar{u}(s)) \| \Delta s.
\]

By the exponential dichotomy and the almost automorphicity of \( f \), we obtain
\[
\lim_{n \to \infty} Tu(t + \alpha_n) = h(t)
\]
for every \( t \in \mathbb{T} \), by Lemma 5.5.
Similarly, one can prove that
\[
\lim_{n \to \infty} h(t + \alpha_n) = Tu(t)
\]
for every \( t \in \mathbb{T} \) and conclude that \( Tu \) is an almost automorphic function. Thus, \( Tu \) is well-defined.

Now, let us prove that \( T \) is a contraction.
\[
\|Tz - Ty\| = \left\| \int_{-\infty}^{t} X(t)PX^{-1}(\sigma(s))[f(s, z) - f(s, y)]\Delta s \right\|
\leq \int_{-\infty}^{t} Ke_{\Theta}(t, \sigma(s))L\|z - y\|\Delta s + \int_{t}^{+\infty} Ke_{\Theta}(s, \sigma(s))L\|z - y\|\Delta s
\leq \frac{1}{\Theta} [Ke_{\Theta}(t, t) - Ke_{\Theta}(t, -\infty)]L\|z - y\| + \frac{1}{\Theta} [K - Ke_{\Theta}(t, +\infty)]L\|z - y\|, \]
by Theorem 2.13. Therefore, we obtain
\[
\|Tz - Ty\| \leq \frac{1}{\gamma} [K - Ke_{\Theta}(t, -\infty)]L\|z - y\| + \frac{1}{\gamma} [K - Ke_{\Theta}(t, +\infty)]L\|z - y\|
\leq L\|z - y\| + \frac{1}{\gamma} (2K + \beta\gamma)\|z - y\| < \|z - y\|, \]
by Theorem 2.14.

It follows that \( T \) is a contraction, then by Banach Fixed-Point Theorem, \( T \) has a unique fixed point. By the definition of \( T \) and Definition 6.1, we obtain that the system (6.1) has a unique solution which is almost automorphic. Therefore, we have the desired result. \( \square \)

**Remark 6.4.** It is clear that the previous theorem remains valid for linear nabla dynamic equations on time scales. In other words, one can prove analogously that the nabla dynamic equation
\[
(6.5) \quad x^{\nabla}(t) = A(t)x(t) + f(t, x(t)),
\]
where \( A : \mathbb{T} \to \mathbb{R}^{n \times n} \) and \( f : \mathbb{T} \times \mathbb{R}^{n} \to \mathbb{R}^{n} \), has an almost automorphic solution, under similar conditions to the ones presented in Theorem 5.6.

Choosing \( \mathbb{T} = \mathbb{R} \) in the Theorem 6.3, we obtain a result for semilinear differential equations. It is the content of the next result.
Corollary 6.5. Let \( f : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^n \) be continuous and almost automorphic with respect to the first variable and \( A : \mathbb{R} \to \mathbb{R}^{n \times n} \) be almost automorphic, continuous and nonsingular and the set \( \{ A^{-1}(t) \}_{t \in \mathbb{R}} \) is bounded. Suppose the equation
\[
\dot{x}(t) = A(t)x(t)
\]
admits an exponential dichotomy with positive constants \( K \) and \( \gamma \) and the following conditions hold:

(i) There exists a constant \( 0 < L < \frac{\gamma}{4K} \) such that
\[
\| f(t, x) - f(t, y) \| \leq L \| x - y \|,
\]
for every \( x, y \in \mathbb{R}^n \) and \( t \in \mathbb{R} \).

Then, the system
\[
\dot{x}(t) = A(t)x(t) + f(t, x(t))
\]
has a unique solution which is almost automorphic.

Taking \( \mathbb{T} = \mathbb{Z} \) in the Theorem 6.3, we obtain a result for semilinear difference equations. See the result below.

Corollary 6.6. Let \( f : \mathbb{Z} \times \mathbb{R}^n \to \mathbb{R}^n \) be regulated and almost automorphic with respect to the first variable and \( A : \mathbb{Z} \to \mathbb{R}^{n \times n} \) be almost automorphic, regulated and nonsingular and \( \{ A^{-1}(k) \}_{k \in \mathbb{Z}} \) is bounded. Also, suppose that \( (I + A(k)) \) is nonsingular and the set \( \{(I + A(k))^{-1}\}_{k \in \mathbb{Z}} \) is bounded. Suppose the equation
\[
x(k + 1) = A(k)x(k)
\]
admits an exponential dichotomy with positive constants \( K \) and \( \gamma \) and the following conditions hold:

(i) There exists a constant \( 0 < L < \frac{\gamma}{2K(2 + \gamma)} \) such that
\[
\| f(k, x) - f(k, y) \| \leq L \| x - y \|,
\]
for every \( x, y \in \mathbb{R}^n \) and \( k \in \mathbb{Z} \).

Then, the system
\[
x(t + 1) = A(t)x(t) + f(t, x(t))
\]
has a unique solution which is almost automorphic.

We can also choose \( \mathbb{T} = h\mathbb{Z} \) in the Theorem 6.3, then it follows a result for a different type of semilinear difference equations. We do not know any result in this direction.

Corollary 6.7. Let \( f : h\mathbb{Z} \times \mathbb{R}^n \to \mathbb{R}^n \) be regulated and almost automorphic with respect to the first variable and \( A : h\mathbb{Z} \to \mathbb{R}^{n \times n} \) be almost automorphic, regulated and nonsingular and \( \{ A^{-1}(k) \}_{k \in h\mathbb{Z}} \) is bounded. Also, suppose that \( (I + A(k)) \) is nonsingular and the set \( \{(I + A(k))^{-1}\}_{k \in h\mathbb{Z}} \) is bounded. Suppose the equation
\[
x(k + h) = A(k)x(k)
\]
admits an exponential dichotomy with positive constants \( K \) and \( \gamma \) and the following conditions hold:
(i) There exists a constant $0 < L < \gamma \frac{\gamma}{2K(2 + h\gamma)}$ such that
\[ \| f(k, x) - f(k, y) \| \leq L \| x - y \|, \]
for every $x, y \in \mathbb{R}^n$ and $k \in h\mathbb{Z}$.

Then, the system
\[ x(k + h) = A(k)x(k) + f(k, x(k)) \]
has a unique solution which is almost automorphic.

Finally, we take $T = P_{a,b}$ in the Theorem 6.3 and we get an interesting result for a different type of equation. We do know any result in this direction. See the following result.

**Corollary 6.8.** Let $f : P_{a,b} \times \mathbb{R}^n \to \mathbb{R}^n$ be almost automorphic with respect to the first variable and, for every $k \in \mathbb{Z}$, be continuous at $[k(a + b), k(a + b) + a)$ and regulated at $k(a + b) + a$ and $A : P_{a,b} \to \mathbb{R}^{n \times n}$ be almost automorphic, and, for every $k \in \mathbb{Z}$, be continuous at $[k(a + b), k(a + b) + a)$, regulated at $k(a + b) + a$ and nonsingular and $\{A^{-1}(t)\}_{t \in P_{a,b}}$ is bounded. Also, suppose that $(I + bA(t))$ is nonsingular and $\{(I + bA(t))^{-1}\}_{t \in P_{a,b}}$ is bounded. Suppose the equation
\[ x^\Delta = A(t)x(t) \]
admits an exponential dichotomy with positive constants $K$ and $\gamma$ and the following conditions hold:

(i) There exists a constant $0 < L < \gamma \frac{\gamma}{2K(2 + b\gamma)}$ such that
\[ \| f(t, x) - f(t, y) \| \leq L \| x - y \|, \]
for every $x, y \in \mathbb{R}^n$ and $t \in P_{a,b}$.

Then, the system
\[ x^\Delta = A(t)x(t) + f(t, x(t)) \]
has a unique solution which is almost automorphic.

7. Examples and Applications

In this section, we present some examples and applications of our main results.

**Example 7.1.** The following economic model is known as a *Keynesian-Cross model with lagged income*. It can be found in [50].

Consider these three equations in a simple closed economy:
\[ D(t) = C(t) + I + G; \quad (7.1) \]
\[ C(t) = C_0 + cy(t); \quad (7.2) \]
\[ y^\Delta(t) = \delta[D^\sigma - y], \quad t \geq a \quad (7.3) \]
where $D$ is the aggregate demand, $y$ is the aggregate income, $C$ is the aggregate consumption, $I$ is the aggregate investment, $G$ is the government spending, $\delta < 1$ is a positive constant known as the *speed of adjustment term* and $C_0, c$ are non-negative constants.
As in [50], we assume that \( G \) and \( I \) are constants in (7.1), and current consumption is assumed to depend on current income in (7.2). Also, equation (7.3) means that the change in income is a fraction of excess demand at \( \sigma(t) \) over income at \( t \) (see [50]).

Putting (7.1) and (7.2) into (7.3), we obtain

\[
y^\Delta = \delta[C_0 + cy^\sigma + I + G - y]
\]

Now, using the formula \( y^\sigma = y + \mu y^\Delta \) and considering \( 1 - \delta c \mu(t) \neq 0 \) for \( t > a \), we have

\[
y^\Delta = \frac{\delta(c - 1)}{1 - \delta c \mu(t)} y + \frac{\delta(c_0 + I + G)}{1 - \delta c \mu(t)}
\]

(7.4)

Then, if \( \mathbb{T} \) is invariant under translation, then we obtain that the graininess function \( \mu(t) \) is almost automorphic, then obviously, by the definition of function \( g \), it follows that \( g \) is an almost automorphic function.

Moreover, if we assume that only one of the following inequalities hold, that is, \( c < 1 \) or \( \mu(t) > \frac{1}{\delta c} \) for every \( t \in \mathbb{T} \), then we obtain that the equation (7.4) admits exponential dichotomy and moreover, \( \{ f(t)^{-1} \} \) is bounded on \( \mathbb{T} \). Assume that \( \mu(t) \neq \frac{1}{\delta} \) for every \( t \in \mathbb{T} \).

In this case, we obtain that the function \( f(t) \) is regressive on \( \mathbb{T} \). Indeed, a function \( f(t) \) is regressive if \( 1 + \mu(t) f(t) \neq 0 \) for every \( t \in \mathbb{T} \). Then,

\[
1 + \mu(t) f(t) \neq 0 \iff 1 + \mu(t) \frac{\delta(c - 1)}{1 - \delta c \mu(t)} \neq 0
\]

\[
\iff 1 - \delta c \mu(t) + \mu(t) \delta(c - 1) \neq 0 \iff 1 - \mu(t) \delta \neq 0,
\]

which implies that \( \mu(t) \neq \frac{1}{\delta} \). Then, it follows that \( f(t) \) is regressive on \( \mathbb{T} \). Therefore, all the hypotheses of Theorem 5.6 are satisfied, then the equation (7.4) has an almost automorphic solution.

The above example generalizes the classical Keynesian-Cross model involving difference equations given in [28]. See [50], for instance. \( \square \)

Now, we present an example which can be found in [53].

**Example 7.2.** Consider the following nonautonomous dynamic equation

(7.5)

\[
x^\Delta(t) = -a(t)x(\sigma(t)) + b(t)
\]

where \( a, b \in C_{\text{rd}}(\mathbb{T}, \mathbb{R}_+) \), \( a, b \) are almost automorphic functions on \( \mathbb{T} \) and \( a \in \mathcal{R} \).

It is clear that the equation given by \( x^\Delta(t) = -a(t)x(\sigma(t)) \) admits exponential dichotomy and also, \( \{ a(t)^{-1} \} \) is bounded on \( \mathbb{T} \). Notice that the function \( a \) takes value in \( \mathbb{R}_+ \) and thus, \( a(t) \neq 0 \), for every \( t \in \mathbb{T} \). Thus, taking \( \mathbb{T} \) invariant under translations, then all the hypotheses of Theorem 5.6 are satisfied, which implies that the equation (7.5) has an almost automorphic solution.

We point out that the equation (7.5) can be used to model many single species models as special cases. For example, taking \( \mathbb{T} = \mathbb{R} \) and \( x(t) = \frac{1}{N(t)} \), then the equation (7.5) reduces to the known *Verhulst logistic equation* given by

\[
\dot{N}(t) = N(t)(a(t) - b(t)N(t)).
\]
On the other hand, taking $T = Z$ and $x(t) = \frac{1}{N(t)}$, then the equation (7.5) reduces to the known *Beverton-Holt equation* given by

$$N(t + 1) = (1 + a(t)) \frac{N(t)}{1 + b(t)N(t)}$$

as explained in [53]. See, for instance, [5] and [49].

Further, if we consider $b(t) = a(t) \ln(c(t))$ and $x(t) = \ln(N(t))$, then the equation (7.5) reduces to the continuous *Gompertz single species model* given by

$$\dot{N}(t) = a(t)N(t) \ln \left( \frac{c(t)}{N(t)} \right).$$

See [25] and [51], for more details.

Finally, taking $T = \mathbb{R}$, we can obtain the discrete *Gompertz single model* which is given by

$$N(t + 1) = N(t) \frac{1}{1 + \mu(t) c(t) \alpha(t)}$$

when $T = \mathbb{Z}$. See, for instance, [52]. □

The next example is inspired in Example 4.20 from [39].

**Example 7.3.** Consider the following equation

$$(7.6) \quad x^{\Delta}(t) = Ax(t) + f(t),$$

where

$$A = \begin{pmatrix} -4 & 0 \\ 0 & -4 \end{pmatrix}, \quad \mu(t) \neq \frac{1}{4} \quad \text{and} \quad f(t) = \begin{pmatrix} \cos \left( \frac{1}{2} \sin t + \sin \sqrt{2}t \right) \\ \sin \sqrt{2}t + \cos t \end{pmatrix}.$$

By the definition, it is clear that $I + \mu(t)A$ is invertible for all $t \in \mathbb{T}$ and thus, $A$ is regressive. Also, notice that $A$ is invertible and $\{A^{-1}\}$ is bounded on $\mathbb{T}$. Moreover, since $\mathbb{T}$ is invariant under translations, the graininess function $\mu$ is bounded and thus, $\{(I + \mu(t)A)^{-1}\}$ is bounded on $\mathbb{T}$.

The function $f$ is almost automorphic on $\mathbb{T}$. Then, using the fact that the eigenvalues of the coefficient matrix in (7.6) are $\lambda_1 = \lambda_2 = -4$ and applying Theorem 5.35 (Putzer Algorithm) from [11], we obtain that the $P$-matrices are given by

$$P_0 = I = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

and

$$P_1 = (A - \lambda_1 I)P_0 = (A + 4I)P_0.$$

Then, using again Theorem 5.35 (Putzer Algorithm) from [11], we obtain

$$r_1^{\Delta}(t) = -4r_1(t), \quad r_1(t_0) = 1$$

$$r_2^{\Delta}(t) = r_1(t) - 4r_2(t), \quad r_2(t_0) = 0.$$

Now, calculating $r_1$, we get

$$r_1(t) = e_{\ominus 4}(t, t_0)$$
and by the Variation Constant Formula, we have
\[ r_2(t) = e_\Theta^4(t, t_0) \int_{t_0}^{t} \frac{1}{1 - 4\mu(s)} \Delta \tau \]

Finally, applying Theorem 5.35 (Putzer Algorithm) from [11] again, we get
\[ e_A(t, t_0) = r_1(t)P_0 + r_2(t)P_1 = e_\Theta^4(t, t_0) \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \]

Therefore, for \( t > s \), we get
\[ \|X(t)P_0X^{-1}(s)\| = \left\| e_\Theta^4(t, t_0) \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} e_\Theta^4(s, t_0) \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \right\| 
= \left\| \begin{pmatrix} e_\Theta^4(t, t_0) & 0 \\ 0 & e_\Theta^4(t, t_0) \end{pmatrix} \begin{pmatrix} e_\Theta^4(s, t_0) & 0 \\ 0 & e_\Theta^4(s, t_0) \end{pmatrix} \right\| 
\leq \sqrt{2}e_\Theta^4(t, s). \]

Taking \( K = 2 \) and \( \gamma = 4 \), we obtain that the equation (7.6) admits exponential dichotomy and thus, by Theorem 5.6, we have
\[
x(t) = \int_{-\infty}^{t} X(t)P_0X^{-1}(\sigma(s))f(s)\Delta s + \int_{t}^{\infty} X(t)(I - P_0)X^{-1}(\sigma(s))f(s)\Delta s 
= \int_{-\infty}^{t} X(t)P_0X^{-1}(\sigma(s))f(s)\Delta s 
= \int_{-\infty}^{t} \left( e_\Theta^4(t, \sigma(s)) \begin{pmatrix} 0 & 0 \\ 0 & e_\Theta^4(t, \sigma(s)) \end{pmatrix} \right) \begin{pmatrix} \cos \left( \frac{1}{2+\sin t+\sin \sqrt{2}t} \right) \\ \sin \sqrt{2}t + \cos t \end{pmatrix} \Delta s.
\]

In the sequel, we present a model which describes high-order Hopfield neural networks on time scales. We borrow some ideas from [40].

**Example 7.4.** Consider the following high-order Hopfield neural networks on time scales:

\[
x_i^\Delta(t) = -c_i(t)x_i(t) + \sum_{j=1}^{n} a_{ij}(f_j(x_j(t))) + \sum_{j=1}^{n} \sum_{l=1}^{n} b_{ijl}(t)g_j(x_j(t))g_l(x_l(t)) + I_i(t),
\]

for \( i = 1, 2, \ldots, n \), where \( n \) corresponds to the number of units in a neural network, \( x_i(t) \) corresponds to the state vector of the \( i \)th unit at the time \( t \), \( c_i(t) \) represents the rate with which the \( i \)th unit will reset its potential to the resting state in isolation when disconnected from the network external inputs, \( a_{ij}(t) \) and \( b_{ijl}(t) \) are the first and second-order connection weights of neural network and \( I_i(t) \) denotes the external inputs at time \( t \) and \( f_j(t) \) and \( g_j(t) \) are the activation functions of signal transmission.

Next, we present a result which can be found in [40], Lemma 2.15 which will be essential to our purposes.

**Lemma 7.5.** Let \( c_i(t) \) be an almost periodic function on \( \mathbb{T} \), where \( c_i(t) > 0, -c_i(t) \in \mathcal{R}, \forall t \in \mathbb{T} \) and
\[
\min_{1 \leq i \leq n} \{ \inf_{t \in \mathbb{T}} c_i(t) \} = \tilde{m} > 0,
\]
then the linear system
\[ x^\Delta(t) = \text{diag}(-c_1(t), -c_2(t), \ldots, -c_n(t))x(t) \]
admits an exponential dichotomy on \( \mathbb{T} \).

**Remark 7.6.** A carefully examination of the proof of the above result reveals that we can change the hypothesis concerning almost periodicity of \( c_i \) by almost automorphicity and obtain the same conclusion. The proof follows similarly for this other case with obvious adaptations.

Now, we assume that the following conditions are satisfied:

(H1) \( c_i, a_{ij}, b_{ijl}, I_i \) are almost automorphic functions, \( -c_i \in \mathcal{R} \) and \( c_i > 0 \) for every \( i, j, l = 1, 2, \ldots, n \).

(H2) There exist positive constants \( M_j, N_j, j = 1, 2, \ldots, n \) such that \( |f_j(x)| \leq M_j \) and \( |g_j(x)| \leq N_j \) for \( j = 1, 2, \ldots, n, x \in \mathbb{R} \).

(H3) Functions \( f_j(u), g_j(u), j = 1, 2, \ldots, n \) satisfy the Lipschitz condition, that is, there exist constants \( L_j, H_j > 0 \) such that \( |f_j(u_1) - f_j(u_2)| \leq L_j|u_1 - u_2|, |g_j(u_1) - g_j(u_2)| \leq H_j|u_1 - u_2|, j = 1, 2, \ldots, n \).

(H4) \( \max_{1 \leq i \leq n} \left\{ \sum_{j=1}^{n} a_{ij} \Delta_j + \sum_{j=1}^{n} \sum_{l=1}^{n} b_{ijl} N_j \Delta_l + \sum_{j=1}^{n} \sum_{l=1}^{n} b_{ijl} N_l \Delta_j / c_i \right\} < 1 \), where

\[ c_i = \inf_{t \in \mathbb{T}} |c_i(t)|, \quad \sigma_i = \sup_{t \in \mathbb{T}} |c_i(t)|, \quad \alpha_{ij} = \sup_{t \in \mathbb{T}} |a_{ij}(t)|, \quad \beta_{ij} = \sup_{t \in \mathbb{T}} |b_{ijl}(t)|, \quad \Delta_t = \sup_{t \in \mathbb{T}} |I_i(t)|. \]

Then, by hypotheses (H1), (H2), (H3) and (H4) and using Lemma 7.5, we obtain that all hypotheses of Theorem 6.3 are satisfied, then the system (7.7) possesses a unique almost automorphic solution.

In the sequel, we present an example which can be found in [53]. The equation of the following example can be known as continuous or discrete Lasota-Wazewska model without delay taking \( \mathbb{T} = \mathbb{R} \) and \( \mathbb{T} = \mathbb{Z} \), respectively. For more details about this model with delays, see [18], [38], [54].

**Example 7.7.** Consider the following dynamic equation on time scales:

\[ x^\Delta(t) = -rx(\sigma(t)) + \eta(t)e^{-\gamma x(t)} \]

where \( r, \gamma \) are all positive conditions and the initial values of (7.8) are also positive.

Suppose that the function \( \eta \) is almost automorphic. In this case, it is bounded and let us denote \( \bar{\eta} = \sup_{t \in \mathbb{T}} \eta(t) \). Also, define the function \( g(t, x(t)) = \eta(t)e^{-\gamma x(t)} \). Then, we have

\[ |g(t, x_1(t)) - g(t, x_2(t))| = |\eta(t)e^{-\gamma x_1(t)} - \eta(t)e^{-\gamma x_2(t)}| \leq \bar{\eta}\gamma |x_1(t) - x_2(t)|. \]

Consider \( \bar{\eta}\gamma < \frac{\gamma_1}{2K(\gamma + \bar{\gamma})} \), where \( K, \gamma_1 \) are the constants from the exponential dichotomy condition and \( \bar{\mu} = \sup_{t \in \mathbb{T}} |\mu(t)| \). Assume also that \( \mathbb{T} \) is invariant under translations, we obtain that all hypotheses of Theorem 6.3 are satisfied which implies that the equation (7.8) has an almost automorphic solution.

Finally, we present an example which can be found in [53]. Notice that for a specific time scale, that is, \( \mathbb{T} = \mathbb{R} \), the equation in the following example reduces to a single artificial effective neuron with dissipation model. See, for instance, [25] and [31].
Example 7.8. Consider the dynamic equation given by
\begin{equation}
(7.9) \quad x^\Delta(t) = -a(t)x(\sigma(t)) + b(t) \tanh(x(t)) + \gamma(t)
\end{equation}
where \(a, b, \gamma \in C_r^d(\mathbb{T}, \mathbb{R}_+)^d\) and \(a, b, \gamma\) are almost automorphic functions and regressive on \(\mathbb{T}\). It is clear that the equation given by \(x^\Delta(t) = -a(t)x(\sigma(t))\) admits exponential dichotomy and also, \(\{a(t)^{-1}\}\) is bounded on \(\mathbb{T}\). Notice that the function \(a\) takes value in \(\mathbb{R}_+\) and thus, \(a(t) \neq 0\), for every \(t \in \mathbb{T}\).

Moreover, notice that \(|\tanh(x_1) - \tanh(x_2)| \leq |x_1 - x_2|\) for \(x_1, x_2 \in \mathbb{T}\). Then, denoting \(g(t, x(t)) = b(t) \tanh(x(t)) + \gamma(t)\), we obtain
\[
|g(t, x_1(t)) - g(t, x_2(t))| = |b(t) \tanh x_1(t) + \gamma(t) - b(t) \tanh x_2(t) - \gamma(t)| \\
\leq |b(t)||x_1(t) - x_2(t)| \leq \tilde{b}|x_1(t) - x_2(t)|,
\]
where \(\tilde{b} = \sup_{t \in \mathbb{T}} |b(t)|\). If we suppose that \(\tilde{b} < \frac{2\mu}{2K(2+\tilde{\gamma})^2}\), where \(\gamma_1, K\) are the constants from the exponential dichotomy and \(\tilde{\mu} = \sup_{t \in \mathbb{T}} |\mu(t)|\) and assume that \(\mathbb{T}\) is invariant under translations, then all hypotheses of Theorem 6.3 are satisfied which implies that the equation (7.9) has an almost automorphic solution.
